**(54) Title:** HYDROGEN GENERATION ASSEMBLIES

**(57) Abstract:** Hydrogen generation assemblies and their components are disclosed. In some embodiments, the assemblies may include a pump controller configured to select a flowrate from a plurality of flowrates based on detected pressure, and to operate the pump at the selected flowrate. In some embodiments, the assemblies may include a purge valve assembly configured to allow at least one pressurized gas to flow through a purge conduit from a pressurized gas assembly to a fuel processing assembly when power to the fuel processing assembly is interrupted. In some embodiments, the assemblies may include a damper controller configured to move a damper between fully open and closed positions based, at least in part, on detected temperature in a hydrogen-producing region. In some embodiments, the assemblies may include a reformer controller configured to operate a fuel processing assembly between run and standby modes based, at least in part, on detected pressure.

## HYDROGEN GENERATION ASSEMBLIES

### Cross-Reference to Related Applications

This application claims priority to U.S. Patent Application Serial No. 61/600096  
5 and entitled HYDROGEN GENERATION ASSEMBLIES, the disclosure of which is incorporated herein by reference.

### Background of the Disclosure

A hydrogen generation assembly is an assembly that converts one or more feedstocks into a product stream containing hydrogen gas as a majority component.  
10 The feedstocks may include a carbon-containing feedstock and, in some embodiments, also may include water. The feedstocks are delivered to a hydrogen-producing region of the hydrogen generation assembly from a feedstock delivery system, typically with the feedstocks being delivered under pressure and at elevated temperatures. The hydrogen-producing region is often associated with a temperature modulating  
15 assembly, such as a heating assembly or cooling assembly, which consumes one or more fuel streams to maintain the hydrogen-producing region within a suitable temperature range for effectively producing hydrogen gas. The hydrogen generation assembly may generate hydrogen gas via any suitable mechanism(s), such as steam reforming, autothermal reforming, pyrolysis, and/or catalytic partial oxidation.

20 The generated or produced hydrogen gas may, however, have impurities. That gas may be referred to as a mixed gas stream that contains hydrogen gas and other gases. Prior to using the mixed gas stream, it must be purified, such as to remove at least a portion of the other gases. The hydrogen generation assembly may therefore include a hydrogen purification device for increasing the hydrogen purity of the mixed

gas stream. The hydrogen purification device may include at least one hydrogen-selective membrane to separate the mixed gas stream into a product stream and a byproduct stream. The product stream contains a greater concentration of hydrogen gas and/or a reduced concentration of one or more of the other gases from the mixed gas stream. Hydrogen purification using one or more hydrogen-selective membranes is a pressure driven separation process in which the one or more hydrogen-selective membranes are contained in a pressure vessel. The mixed gas stream contacts the mixed gas surface of the membrane(s), and the product stream is formed from at least a portion of the mixed gas stream that permeates through the membrane(s). The pressure vessel is typically sealed to prevent gases from entering or leaving the pressure vessel except through defined inlet and outlet ports or conduits.

The product stream may be used in a variety of applications. One such application is energy production, such as in electrochemical fuel cells. An electrochemical fuel cell is a device that converts fuel and an oxidant to electricity, a reaction product, and heat. For example, fuel cells may convert hydrogen and oxygen into water and electricity. In those fuel cells, the hydrogen is the fuel, the oxygen is the oxidant, and the water is a reaction product. Fuel cell stacks include a plurality of fuel cells and may be utilized with a hydrogen generation assembly to provide an energy production assembly.

Examples of hydrogen generation assemblies, hydrogen processing assemblies, and/or components of those assemblies are described in U.S. Patent Nos. 5,861,137; 6,319,306; 6,494,937; 6,562,111; 7,063,047; 7,306,868; 7,470,293; 7,601,302; 7,632,322; U.S. Patent Application Publication Nos. 2006/0090397; 2006/0272212;

2007/0266631; 2007/0274904; 2008/0085434; 2008/0138678; 2008/0230039; 2010/0064887; and U.S. Patent Application Serial No. 13/178,098. The complete disclosures of the above patents and patent application publications are hereby incorporated by reference for all purposes.

5

### Summary of the Disclosure

Some embodiments may provide a hydrogen generation assembly. In some embodiments, the hydrogen generation assembly may include a fuel processing assembly configured to receive a feed stream and produce a product hydrogen stream from the feed stream. The hydrogen generation assembly may additionally include a feed assembly configured to deliver the feed stream to the fuel processing assembly. The feed assembly may include a feed tank configured to contain feedstock for the feed stream, and a feed conduit fluidly connecting the feed tank and the fuel processing assembly. The feed assembly may additionally include a pump configured to deliver the feed stream at a plurality of flowrates to the fuel processing assembly via the feed conduit. The hydrogen generation assembly may further include a control system. The control system may include a feed sensor assembly configured to detect pressure in the feed conduit downstream from the pump. The control system may additionally include a pump controller configured to select a flowrate from the plurality of flowrates based on the detected pressure in the feed conduit, and to operate the pump at the selected flowrate.

In some embodiments, the hydrogen generation assembly may include a fuel processing assembly configured to receive a feed stream and produce a product hydrogen stream from the feed stream. The hydrogen generation assembly may

additionally include a pressurized gas assembly configured to receive at least one container of pressurized gas that is configured to purge the fuel processing assembly. The hydrogen generation assembly may further include a purge conduit configured to fluidly connect the pressurized gas assembly and the fuel processing assembly. The

5 hydrogen generation assembly may additionally include a purge valve assembly configured to allow the at least one pressurized gas to flow through the purge conduit from the pressurized gas assembly to the fuel processing assembly when power to the fuel processing assembly is interrupted.

In some embodiments, the hydrogen generation assembly may include a fuel

10 processing assembly configured to receive a feed stream and to be operable among a plurality of modes, including a run mode in which the fuel processing assembly produces a product hydrogen stream from the feed stream, and a standby mode in which the fuel processing assembly does not produce the product hydrogen stream from the feed stream. The hydrogen generation assembly may additionally include a

15 buffer tank configured to contain the product hydrogen stream, and a product conduit fluidly connecting the fuel processing assembly and the buffer tank. The hydrogen generation assembly may further include a tank sensor assembly configured to detect pressure in the buffer tank, and a control assembly configured to operate the fuel processing assembly between the run and standby modes based, at least in part, on the

20 detected pressure in the buffer tank.

Some embodiments may provide a steam reforming hydrogen generation assembly configured to receive at least one feed stream and generate a reformat stream containing hydrogen gas as a majority component and other gases. In some

embodiments, the steam reforming hydrogen generation assembly may include an enclosure having an exhaust port, and a hydrogen-producing region contained within the enclosure and configured to produce, via a steam reforming reaction, the reformat stream from the at least one feed stream. The steam reforming hydrogen generation  
5 assembly may additionally include a reformer sensor assembly configured to detect temperature in the hydrogen-producing region. The steam reforming hydrogen generation assembly may further include a heating assembly configured to receive at least one air stream and at least one fuel stream and to combust the at least one fuel stream within a combustion region contained within the enclosure producing a heated  
10 exhaust stream for heating at least the hydrogen-producing region to at least a minimum hydrogen-producing temperature. The steam reforming hydrogen generation assembly may additionally include a damper moveably connected to the exhaust port and configured to move among a plurality of positions including a fully open position in which the damper allows the heated exhaust stream to flow through the exhaust port, a  
15 closed position in which the damper prevents the heated exhaust stream from flowing through the exhaust port, and a plurality of intermediate open positions between the fully open and closed positions. The steam reforming hydrogen generation assembly may further include a damper controller configured to move the damper between the fully open and closed positions based, at least in part, on the detected temperature in  
20 the hydrogen-producing region.

#### Brief Description of the Drawings

10 Detailed Description of the Disclosure

Fig. 1 shows an example of a hydrogen generation assembly 20. Unless specifically excluded hydrogen generation assembly may include one or more components of other hydrogen generation assemblies described in this disclosure. The hydrogen generation assembly may include any suitable structure configured to  
15 generate a product hydrogen stream 21. For example, the hydrogen generation assembly may include a feedstock delivery system 22 and a fuel processing assembly 24. The feedstock delivery system may include any suitable structure configured to selectively deliver at least one feed stream 26 to the fuel processing assembly.

In some embodiments, feedstock delivery system 22 may additionally include  
20 any suitable structure configured to selectively deliver at least one fuel stream 28 to a burner or other heating assembly of fuel processing assembly 24. In some embodiments, feed stream 26 and fuel stream 28 may be the same stream delivered to different parts of the fuel processing assembly. The feedstock delivery system may

include any suitable delivery mechanisms, such as a positive displacement or other suitable pump or mechanism for propelling fluid streams. In some embodiments, feedstock delivery system may be configured to deliver feed stream(s) 26 and/or fuel stream(s) 28 without requiring the use of pumps and/or other electrically powered fluid-delivery mechanisms. Examples of suitable feedstock delivery systems that may be used with hydrogen generation assembly 20 include the feedstock delivery systems described in U.S. Patent Nos. 7,470,293 and 7,601,302, and U.S. Patent Application Publication No. 2006/0090397. The complete disclosures of the above patents and patent application are hereby incorporated by reference for all purposes.

Feed stream 26 may include at least one hydrogen-production fluid 30, which may include one or more fluids that may be utilized as reactants to produce product hydrogen stream 21. For example, the hydrogen-production fluid may include a carbon-containing feedstock, such as at least one hydrocarbon and/or alcohol. Examples of suitable hydrocarbons include methane, propane, natural gas, diesel, kerosene, gasoline, etc. Examples of suitable alcohols include methanol, ethanol, polyols (such as ethylene glycol and propylene glycol), etc. Additionally, hydrogen-production fluid 30 may include water, such as when fuel processing assembly generates the product hydrogen stream via steam reforming and/or autothermal reforming. When fuel processing assembly 24 generates the product hydrogen stream via pyrolysis or catalytic partial oxidation, feed stream 26 does not contain water.

In some embodiments, feedstock delivery system 22 may be configured to deliver a hydrogen-production fluid 30 that contains a mixture of water and a carbon-containing feedstock that is miscible with water (such as methanol and/or another

water-soluble alcohol). The ratio of water to carbon-containing feedstock in such a fluid stream may vary according to one or more factors, such as the particular carbon-containing feedstock being used, user preferences, design of the fuel processing assembly, mechanism(s) used by the fuel processing assembly to generate the product hydrogen stream etc. For example, the molar ratio of water to carbon may be approximately 1:1 to 3:1. Additionally, mixtures of water and methanol may be delivered at or near a 1:1 molar ratio (37 weight % water, 63 weight % methanol), while mixtures of hydrocarbons or other alcohols may be delivered at a water-to-carbon molar ratio greater than 1:1.

When fuel processing assembly 24 generates product hydrogen stream 21 via reforming, feed stream 26 may include, for example, approximately 25-75 volume % methanol or ethanol (or another suitable water-miscible carbon-containing feedstock) and approximately 25-75 volume % water. For feed streams that at least substantially include methanol and water, those streams may include approximately 50-75 volume % methanol and approximately 25-50 volume % water. Streams containing ethanol or other water-miscible alcohols may contain approximately 25-60 volume % alcohol and approximately 40-75 volume % water. An example of a feed stream for hydrogen generating assembly 20 that utilizes steam reforming or autothermal reforming contains 69 volume % methanol and 31 volume % water.

Although feedstock delivery system 22 is shown to be configured to deliver a single feed stream 26, the feedstock delivery system may be configured to deliver two or more feed streams 26. Those streams may contain the same or different feedstocks and may have different compositions, at least one common component, no common

components, or the same compositions. For example, a first feed stream may include a first component, such as a carbon-containing feedstock and a second feed stream may include a second component, such as water. Additionally, although feedstock delivery system 22 may, in some embodiments, be configured to deliver a single fuel stream 28, the feedstock delivery system may be configured to deliver two or more fuel streams. The fuel streams may have different compositions, at least one common component, no common components, or the same compositions. Moreover, the feed and fuel streams may be discharged from the feedstock delivery system in different phases. For example, one of the streams may be a liquid stream while the other is a gas stream. In some embodiments, both of the streams may be liquid streams, while in other embodiments both of the streams may be gas streams. Furthermore, although hydrogen generation assembly 20 is shown to include a single feedstock delivery system 22, the hydrogen generation assembly may include two or more feedstock delivery systems 22.

Fuel processing assembly 24 may include a hydrogen-producing region 32 configured to produce an output stream 34 containing hydrogen gas via any suitable hydrogen-producing mechanism(s). The output stream may include hydrogen gas as at least a majority component and may include additional gaseous component(s). Output stream 34 may therefore be referred to as a "mixed gas stream" that contains hydrogen gas as its majority component but which includes other gases.

Hydrogen-producing region 32 may include any suitable catalyst-containing bed or region. When the hydrogen-producing mechanism is steam reforming, the hydrogen-producing region may include a suitable steam reforming catalyst 36 to facilitate production of output stream(s) 34 from feed stream(s) 26 containing a carbon-

containing feedstock and water. In such an embodiment, fuel processing assembly 24 may be referred to as a “steam reformer,” hydrogen-producing region 32 may be referred to as a “reforming region,” and output stream 34 may be referred to as a “reformat stream.” The other gases that may be present in the reformat stream may include carbon monoxide, carbon dioxide, methane, steam, and/or unreacted carbon-containing feedstock.

When the hydrogen-producing mechanism is autothermal reforming, hydrogen-producing region 32 may include a suitable autothermal reforming catalyst to facilitate the production of output stream(s) 34 from feed stream(s) 26 containing water and a carbon-containing feedstock in the presence of air. Additionally, fuel processing assembly 24 may include an air delivery assembly 38 configured to deliver air stream(s) to the hydrogen-producing region.

In some embodiments, fuel processing assembly 24 may include a purification (or separation) region 40, which may include any suitable structure configured to produce at least one hydrogen-rich stream 42 from output (or mixed gas) stream 34. Hydrogen-rich stream 42 may include a greater hydrogen concentration than output stream 34 and/or a reduced concentration of one or more other gases (or impurities) that were present in that output stream. Product hydrogen stream 21 includes at least a portion of hydrogen-rich stream 42. Thus, product hydrogen stream 21 and hydrogen-rich stream 42 may be the same stream and have the same composition and flow rates. Alternatively, some of the purified hydrogen gas in hydrogen-rich stream 42 may be stored for later use, such as in a suitable hydrogen storage assembly and/or consumed

by the fuel processing assembly. Purification region 40 also may be referred to as a “hydrogen purification device” or a “hydrogen processing assembly.”

In some embodiments, purification region 40 may produce at least one byproduct stream 44, which may contain no hydrogen gas or some hydrogen gas. The byproduct  
5 stream may be exhausted, sent to a burner assembly and/or other combustion source, used as a heated fluid stream, stored for later use, and/or otherwise utilized, stored, and/or disposed. Additionally, purification region 40 may emit the byproduct stream as a continuous stream responsive to the deliver of output stream 34, or may emit that stream intermittently, such as in a batch process or when the byproduct portion of the  
10 output stream is retained at least temporarily in the purification region.

Fuel processing assembly 24 may include one or more purification regions configured to produce one or more byproduct streams containing sufficient amounts of hydrogen gas to be suitable for use as a fuel stream (or a feedstock stream) for a heating assembly for the fuel processing assembly. In some embodiments, the  
15 byproduct stream may have sufficient fuel value or hydrogen content to enable a heating assembly to maintain the hydrogen-producing region at a desired operating temperature or within a selected range of temperatures. For example, the byproduct stream may include hydrogen gas, such as 10-30 weight % hydrogen gas, 15-25 weight % hydrogen gas, 20-30 weight % hydrogen gas, at least 10 or 15 weight % hydrogen  
20 gas, at least 20 weight % hydrogen gas, etc.

Purification region 40 may include any suitable structure configured to reduce the concentration of at least one component of output stream 21. In most applications, hydrogen-rich stream 42 will have a greater hydrogen concentration than output stream

(or mixed gas stream) 34. The hydrogen-rich stream also may have a reduced concentration of one or more non-hydrogen components that were present in output stream 34 with the hydrogen concentration of the hydrogen-rich stream being more, the same, or less than the output stream. For example, in conventional fuel cell systems, carbon monoxide may damage a fuel cell stack if it is present in even a few parts per million, while other non-hydrogen components that may be present in output stream 34, such as water, will not damage the stack even if present in much greater concentrations. Therefore, in such an application, the purification region may not increase the overall hydrogen concentration but will reduce the concentration of one or more non-hydrogen components that are harmful, or potentially harmful, to the desired application for the product hydrogen stream.

Examples of suitable devices for purification region 40 include one or more hydrogen-selective membranes 46, chemical carbon monoxide removal assemblies 48, and/or pressure swing adsorption (PSA) systems 50. Purification region 40 may include more than one type of purification device and the devices may have the same or different structures and/or operate by the same or difference mechanism(s). Fuel processing assembly 24 may include at least one restrictive orifice and/or other flow restrictor downstream of the purification region(s), such as associated with one or more product hydrogen stream(s), hydrogen-rich stream(s), and/or byproduct stream(s).

Hydrogen-selective membranes 46 are permeable to hydrogen gas, but are at least substantially (if not completely) impermeable to other components of output stream 34. Membranes 46 may be formed of any hydrogen-permeable material suitable for use in the operating environment and parameters in which purification region 40 is

operated. Examples of suitable materials for membranes 46 include palladium and palladium alloys, and especially thin films of such metals and metal alloys. Palladium alloys have proven particularly effective, especially palladium with 35 weight % to 45 weight % copper. A palladium-copper alloy that contains approximately 40 weight %  
5 copper has proven particularly effective, although other relative concentrations and components may be used. Another especially effective alloy is palladium with 2 weight % to 10 weight % gold, especially palladium with 5 weight % gold. When palladium and palladium alloys are used, hydrogen-selective membranes 46 may sometimes be referred to as "foils."

10 Chemical carbon monoxide removal assemblies 48 are devices that chemically react carbon monoxide and/or other undesirable components of output stream 34 to form other compositions that are not as potentially harmful. Examples of chemical carbon monoxide removal assemblies include water-gas shift reactors that are configured to produce hydrogen gas and carbon dioxide from water and carbon  
15 monoxide, partial oxidation reactors that are configured to convert carbon monoxide and oxygen (usually from air) into carbon dioxide, and methanation reactors that are configured to convert carbon monoxide and hydrogen to methane and water. Fuel processing assembly 24 may include more than one type and/or number of chemical removal assemblies 48.

20 Pressure swing adsorption (PSA) is a chemical process in which gaseous impurities are removed from output stream 34 based on the principle that certain gases, under the proper conditions of temperature and pressure, will be adsorbed onto an adsorbent material more strongly than other gases. Typically, the non-hydrogen

impurities are adsorbed and removed from output stream 34. Adsorption of impurity gases occurs at elevated pressure. When the pressure is reduced, the impurities are desorbed from the adsorbent material, thus regenerating the adsorbent material. Typically, PSA is a cyclic process and requires at least two beds for continuous (as  
5 opposed to batch) operation. Examples of suitable adsorbent materials that may be used in adsorbent beds are activated carbon and zeolites. PSA system 50 also provides an example of a device for use in purification region 40 in which the byproducts, or removed components, are not directly exhausted from the region as a gas stream concurrently with the purification of the output stream. Instead, these byproduct  
10 components are removed when the adsorbent material is regenerated or otherwise removed from the purification region.

In Fig. 1, purification region 40 is shown within fuel processing assembly 24. The purification region may alternatively be separately located downstream from the fuel processing assembly, as is schematically illustrated in dash-dot lines in Fig. 1.  
15 Purification region 40 also may include portions within and external to the fuel processing assembly.

Fuel processing assembly 24 also may include a temperature modulating assembly in the form of a heating assembly 52. The heating assembly may be configured to produce at least one heated exhaust stream (or combustion stream) 54  
20 from at least one heating fuel stream 28, typically as combusted in the presence of air. Heated exhaust stream 54 is schematically illustrated in Fig. 1 as heating hydrogen-producing region 32. Heating assembly 52 may include any suitable structure configured to generate the heated exhaust stream, such as a burner or combustion

catalyst in which a fuel is combusted with air to produce the heated exhaust stream. The heating assembly may include an ignitor or ignition source 58 that is configured to initiate the combustion of fuel. Examples of suitable ignition sources include one or more spark plugs, glow plugs, combustion catalyst, pilot lights, piezoelectric ignitors, spark igniters, hot surface igniters, etc.

In some embodiments, heating assembly 52 may include a burner assembly 60 and may be referred to as a combustion-based, or combustion-driven, heating assembly. In a combustion-based heating assembly, heating assembly 52 may be configured to receive at least one fuel stream 28 and to combust the fuel stream in the presence of air to provide a hot combustion stream 54 that may be used to heat at least the hydrogen-producing region of the fuel processing assembly. Air may be delivered to the heating assembly via a variety of mechanisms. For example, an air stream 62 may be delivered to the heating assembly as a separate stream, as shown in Fig. 1. Alternatively, or additionally, air stream 62 may be delivered to the heating assembly with at least one of the fuel streams 28 for heating assembly 52 and/or drawn from the environment within which the heating assembly is utilized.

Combustion stream 54 may additionally, or alternatively, be used to heat other portions of the fuel processing assembly and/or fuel cell systems with which the heating assembly is used. Additionally, other configuration and types of heating assemblies 52 may be used. For example, heating assembly 52 may be an electrically powered heating assembly that is configured to heat at least hydrogen-producing region 32 of fuel processing assembly 24 by generating heat using at least one heating element, such as a resistive heating element. In those embodiments, heating assembly 52 may

not receive and combust a combustible fuel stream to heat the hydrogen-producing region to a suitable hydrogen-producing temperature. Examples of heating assemblies are disclosed in U.S. Patent No. 7,632,322, the complete disclosure of which is hereby incorporated by reference for all purposes.

5           Heating assembly 52 may be housed in a common shell or housing with the hydrogen-producing region and/or separation region (as further discussed below). The heating assembly may be separately positioned relative to hydrogen-producing region 32 but in thermal and/or fluid communication with that region to provide the desired heating of at least the hydrogen-producing region. Heating assembly 52 may be located  
10           partially or completely within the common shell, and/or at least a portion (or all) of the heating assembly may be located external that shell. When the heating assembly is located external the shell, the hot combustion gases from burner assembly 60 may be delivered via suitable heat transfer conduits to one or more components within the shell.

          The heating assembly also may be configured to heat feedstock delivery system  
15           22, the feedstock supply streams, hydrogen-producing region 32, purification (or separation) region 40, or any suitable combination of those systems, streams, and regions. Heating of the feedstock supply streams may include vaporizing liquid reactant streams or components of the hydrogen-production fluid used to produce hydrogen gas in the hydrogen-producing region. In that embodiment, fuel processing assembly 24  
20           may be described as including a vaporization region 64. The heating assembly may additionally be configured to heat other components of the hydrogen generation assembly. For example, the heated exhaust stream may be configured to heat a

pressure vessel and/or other canister containing the heating fuel and/or the hydrogen-production fluid that forms at least portions of feed stream 26 and fuel stream 28.

Heating assembly 52 may achieve and/or maintain in hydrogen-producing region 32 any suitable temperatures. Steam reformers typically operate at temperatures in the range of 200°C and 900°C. However, temperatures outside this range are within the scope of this disclosure. When the carbon-containing feedstock is methanol, the steam reforming reaction will typically operate in a temperature range of approximately 200-500°C. Example subsets of that range include 350-450°C, 375-425°C, and 375-400°C. When the carbon-containing feedstock is a hydrocarbon, ethanol or another alcohol, a temperature range of approximately 400-900°C will typically be used for the steam reforming reaction. Example subsets of that range include 750-850°C, 725-825°C, 650-750°C, 700-800°C, 700-900°C, 500-800°C, 400-600°C, and 600-800°C. Hydrogen-producing region 32 may include two or more zones, or portions, each of which may be operated at the same or at different temperatures. For example, when the hydrogen-production fluid includes a hydrocarbon, hydrogen-producing region 32 may include two different hydrogen-producing portions, or regions, with one operating at a lower temperature than the other to provide a pre-reforming region. In those embodiments, the fuel processing assembly may also be referred to as including two or more hydrogen-producing regions.

Fuel stream 28 may include any combustible liquid(s) and/or gas(es) that are suitable for being consumed by heating assembly 52 to provide the desired heat output. Some fuel streams may be gases when delivered and combusted by heating assembly 52, while others may be delivered to the heating assembly as a liquid stream. Examples

of suitable heating fuels for fuel streams 28 include carbon-containing feedstocks, such as methanol, methane, ethane, ethanol, ethylene, propane, propylene, butane, etc. Additional examples include low molecular weight condensable fuels, such as liquefied petroleum gas, ammonia, lightweight amines, dimethyl ether, and low molecular weight hydrocarbons. Yet other examples include hydrogen and carbon monoxide. In 5 embodiments of hydrogen generation assembly 20 that include a temperature modulating assembly in the form of a cooling assembly instead of a heating assembly (such as may be used when an exothermic hydrogen-generating process — e.g., partial oxidation — is utilized instead of an endothermic process such as steam reforming), the feedstock delivery system may be configured to supply a fuel or coolant stream to the 10 assembly. Any suitable fuel or coolant fluid may be used.

Fuel processing assembly 24 may additionally include a shell or housing 66 in which at least hydrogen-producing region 32 is contained, as shown in Fig. 1. In some embodiments, vaporization region 64 and/or purification region 40 may additionally be 15 contained within the shell. Shell 66 may enable components of the steam reformer or other fuel processing mechanism to be moved as a unit. The shell also may protect components of the fuel processing assembly from damage by providing a protective enclosure and/or may reduce the heating demand of the fuel processing assembly because components may be heated as a unit. Shell 66 may include insulating material 20 68, such as a solid insulating material, blanket insulating material, and/or an air-filled cavity. The insulating material may be internal the shell, external the shell, or both. When the insulating material is external a shell, fuel processing assembly 24 may further include an outer cover or jacket 70 external the insulation, as schematically

illustrated in Fig. 1. The fuel processing assembly may include a different shell that includes additional components of the fuel processing assembly, such as feedstock delivery system 22 and/or other components.

One or more components of fuel processing assembly 24 may either extend  
5 beyond the shell or be located external the shell. For example, purification region 40 may be located external shell 66, such as being spaced-away from the shell but in fluid communication by suitable fluid-transfer conduits. As another example, a portion of hydrogen-producing region 32 (such as portions of one or more reforming catalyst beds) may extend beyond the shell, such as indicated schematically with a dashed line  
10 representing an alternative shell configuration in Fig. 1. Examples of suitable hydrogen generation assemblies and its components are disclosed in U.S. Patent Nos. 5,861,137; 5,997,594; and 6,221,117, the complete disclosures of which are hereby incorporated by reference for all purposes.

Another example of hydrogen generation assembly 20 is shown in Fig. 2, and is  
15 generally indicated at 72. Unless specifically excluded, hydrogen generation assembly 72 may include one or more components of hydrogen generation assembly 20. Hydrogen-generation assembly 72 may include a feedstock delivery system 74, a vaporization region 76, a hydrogen-producing region 78, and a heating assembly 80, as shown in Fig. 2. In some embodiments, hydrogen generation assembly 20 also may  
20 include a purification region 82.

The feedstock delivery system may include any suitable structure configured to deliver one or more feed and/or fuel streams to one or more other components of the hydrogen-generation assembly. For example, feedstock delivery system may include a

feedstock tank (or container) 84 and a pump 86. The feedstock tank may contain any suitable hydrogen-production fluid 88, such as water and a carbon-containing feedstock (e.g., a methanol/water mixture). Pump 86 may have any suitable structure configured to deliver the hydrogen-production fluid, which may be in the form of at least one liquid-  
5 containing feed stream 90 that includes water and a carbon-containing feedstock, to vaporization region 76 and/or hydrogen-producing region 78.

Vaporization region 76 may include any suitable structure configured to receive and vaporize at least a portion of a liquid-containing feed stream, such as liquid-containing feed stream 90. For example, vaporization region 76 may include a vaporizer  
10 92 configured to at least partially transform liquid-containing feed stream 90 into one or more vapor feed streams 94. The vapor feed streams may, in some embodiments, include liquid. An example of a suitable vaporizer is a coiled tube vaporizer, such as a coiled stainless steel tube.

Hydrogen-producing region 78 may include any suitable structure configured to  
15 receive one or more feed streams, such as vapor feed stream(s) 94 from the vaporization region, to produce one or more output streams 96 containing hydrogen gas as a majority component and other gases. The hydrogen-producing region may produce the output stream via any suitable mechanism(s). For example, hydrogen-producing region 78 may generate output stream(s) 96 via a steam reforming reaction. In that  
20 example, hydrogen-producing region 78 may include a steam reforming region 97 with a reforming catalyst 98 configured to facilitate and/or promote the steam reforming reaction. When hydrogen-producing region 78 generates output stream(s) 96 via a steam reforming reaction, hydrogen generation assembly 72 may be referred to as a

“steam reforming hydrogen generation assembly” and output stream 96 may be referred to as a “reformat stream.”

Heating assembly 80 may include any suitable structure configured to produce at least one heated exhaust stream 99 for heating one or more other components of the hydrogen generation assembly 72. For example, the heating assembly may heat the vaporization region to any suitable temperature(s), such as at least a minimum vaporization temperature or the temperature in which at least a portion of the liquid-containing feed stream is vaporized to form the vapor feed stream. Additionally, or alternatively, heating assembly 80 may heat the hydrogen-producing region to any suitable temperature(s), such as at least a minimum hydrogen-producing temperature or the temperature in which at least a portion of the vapor feed stream is reacted to produce hydrogen gas to form the output stream. The heating assembly may be in thermal communication with one or more components of the hydrogen generation assembly, such as the vaporization region and/or hydrogen-producing region.

The heating assembly may include a burner assembly 100, at least one air blower 102, and an igniter assembly 104, as shown in Fig. 2. The burner assembly may include any suitable structure configured to receive at least one air stream 106 and at least one fuel stream 108 and to combust the at least one fuel stream within a combustion region 110 to produce heated exhaust stream 99. The fuel stream may be provided by feedstock delivery system 74 and/or purification region 82. The combustion region may be contained within an enclosure of the hydrogen generation assembly. Air blower 102 may include any suitable structure configured to generate air stream(s) 106.

Igniter assembly 104 may include any suitable structure configured to ignite fuel stream(s) 108.

Purification region 82 may include any suitable structure configured to produce at least one hydrogen-rich stream 112, which may include a greater hydrogen  
5 concentration than output stream 96 and/or a reduced concentration of one or more other gases (or impurities) that were present in that output stream. The purification region may produce at least one byproduct stream or fuel stream 108, which may be sent to burner assembly 100 and used as a fuel stream for that assembly, as shown in Fig. 2. Purification region 82 may include a flow restricting orifice 111, a filter assembly  
10 114, a membrane assembly 116, and a methanation reactor assembly 118. The filter assembly (such as one or more hot gas filters) may be configured to remove impurities from output stream 96 prior to the hydrogen purification membrane assembly.

Membrane assembly 116 may include any suitable structure configured to receive output or mixed gas stream(s) 96 that contains hydrogen gas and other gases,  
15 and to generate permeate or hydrogen-rich stream(s) 112 containing a greater concentration of hydrogen gas and/or a lower concentration of other gases than the mixed gas stream. Membrane assembly 116 may incorporate hydrogen-permeable (or hydrogen-selective) membranes that are planar or tubular, and more than one hydrogen-permeable membrane may be incorporated into membrane assembly 116.  
20 The permeate stream(s) may be used for any suitable applications, such as for one or more fuel cells. In some embodiments, the membrane assembly may generate a byproduct or fuel stream 108 that includes at least a substantial portion of the other gases. Methanation reactor assembly 118 may include any suitable structure configured

to convert carbon monoxide and hydrogen to methane and water. Although purification region 82 is shown to include flow restricting orifice 111, filter assembly 114, membrane assembly 116, and methanation reactor assembly 118, the purification region may have less than all of those assemblies, and/or may alternatively, or additionally, include one or more other components configured to purify output stream 96. For example, purification region 82 may include only membrane assembly 116.

In some embodiments, hydrogen generation assembly 72 may include a shell or housing 120 which may at least partially contain one or more other components of that assembly. For example, shell 120 may at least partially contain vaporization region 76, hydrogen-producing region 78, heating assembly 80, and/or purification region 82, as shown in Fig. 2. Shell 120 may include one or more exhaust ports 122 configured to discharge at least one combustion exhaust stream 124 produced by heating assembly 80.

Hydrogen generation assembly 72 may, in some embodiments, include a control system 126, which may include any suitable structure configured to control operation of hydrogen generation assembly 72. For example, control assembly 126 may include a control assembly 128, at least one valve 130, at least one pressure relief valve 132, and one or more temperature measurement devices 134. Control assembly 128 may detect temperatures in the hydrogen-producing region and/or purification regions via the temperature measurement device 134, which may include one or more thermocouples and/or other suitable devices. Based on the detected temperatures, the control assembly and/or an operator of the control system may adjust delivery of feed stream 90 to vaporization region 76 and/or hydrogen-producing region 78 via valve(s) 130 and

pump(s) 86. Valve(s) 130 may include a solenoid valve and/or any suitable valve(s). Pressure relief valve(s) 132 may be configured to ensure that excess pressure in the system is relieved.

In some embodiments, hydrogen generation assembly 72 may include a heat exchange assembly 136, which may include one or more heat exchangers 138 configured to transfer heat from one portion of the hydrogen generation assembly to another portion. For example, heat exchange assembly 136 may transfer heat from hydrogen-rich stream 112 to feed stream 90 to raise the temperature of the feed stream prior to entering vaporization region 76, as well as to cool hydrogen-rich stream 112.

Another example of hydrogen generation assembly 20 is generally indicated at 140 in Fig. 3. Unless specifically excluded, hydrogen generation assembly 140 may include one or more components of one or more other hydrogen generation assemblies described in this disclosure. Hydrogen generation assembly 140 may include a feedstock delivery system or feed assembly 142 and a fuel processing assembly 144 configured to receive at least one feed stream from the feedstock delivery system and produce one or more product hydrogen stream(s), such as a hydrogen gas stream, from the feed stream(s).

The feedstock delivery system may include any suitable structure configured to deliver one or more feed and/or fuel streams to one or more other components of the hydrogen generation assembly, such as fuel processing assembly 144. For example, the feedstock delivery system may include a feedstock tank or feed tank (and/or container) 146, a feed conduit 148, a pump 150, and a control system 152. The feed tank may contain feedstock for one or more feed streams of the fuel processing

assembly. For example, feed tank 146 may contain any suitable hydrogen-production fluid, such as water and a carbon-containing feedstock (e.g., a methanol/water mixture).

Feed conduit 148 may fluidly connect feed tank 146 with fuel processing assembly 144. The feed conduit may include a feed portion 154 and a bypass portion 156. The bypass portion may be configured to prevent overpressurization in the feed conduit, in the fuel processing assembly, and/or in one or more other components of hydrogen generation assembly 140. For example, bypass portion 156 may include a valve assembly 158, such as a pressure relief valve or a check valve.

Pump 150 may have any suitable structure configured to deliver one or more feed and/or fuel streams to the fuel processing assembly at a plurality of flowrates to fuel processing assembly 144 via, for example, feed conduit 148. For example, pump 150 may be a variable-speed pump (or a pump that includes a variable speed motor) that injects the feed and/or fuel streams into the fuel processing assembly under pressure. The pump may operate at a speed based on a control signal from the control system. For example, pump 150 may operate or turn at a higher speed (which results in the pump discharging the feed and/or fuel streams at a higher flowrate) when the control signal increases in magnitude, while the pump may operate or turn at a lower speed (which results in the pump discharging the feed and/or fuel streams at a lower flowrate) when the control signal decreases in magnitude.

Pressure in the fuel processing assembly (such as in the hydrogen-producing region of the fuel processing assembly) may increase with higher pump flowrates and may decrease with lower pump flowrates. For example, one or more fixed flow restriction devices in the fuel processing assembly may cause a proportional increase in

pressure with higher pump flowrates, and a proportional decrease in pressure with lower pump flowrates. Because feed conduit 148 fluidly connects the feedstock delivery system and the fuel processing assembly, an increase (or decrease) in pressure in the fuel processing assembly may result in an increase (or decrease) in pressure in the  
5 feed conduit downstream from pump 150.

Control system 152 may include any suitable structure configured to control and/or operate pump 150 and/or other controlled devices of hydrogen generation assembly 140. For example, control system 152 may include a sensor assembly 160, a control assembly 162, and communication linkages 164.

10 The sensor assembly may include any suitable structure configured to detect and/or measure one or more suitable operating variables and/or parameters in the hydrogen generation assembly and/or generate one or more signals based on the detected and/or measured operating variable(s) and/or parameter(s). For example, the sensor assembly may detect mass, volume, flow, temperature, electrical current,  
15 pressure, refractive index, thermal conductivity, density, viscosity, optical absorbance, electrical conductivity, and/or other suitable variable(s), and/or parameter(s). In some embodiments, the sensor assembly may detect one or more triggering events. A “triggering event,” as used herein, is a measurable event in which a predetermined threshold value or range of values representative of a predetermined amount of one or  
20 more of the components forming one or more streams associated with the hydrogen generation assembly is reached or exceeded.

For example, sensor assembly 160 may include one or more sensors 166 configured to detect pressure, temperature, flowrate, volume, and/or other parameters.

Sensors 166 may, for example, include at least one feed sensor 168 configured to detect one or more suitable operating variables, parameters, and/or triggering events in feed conduit 148. The feed sensor may be configured to detect, for example, pressure in the feed conduit and/or generate one or more signals based on the detected  
5 pressure.

Control assembly 162 may be configured to communicate with sensor assembly 160 and pump 150 (and/or other controlled devices of hydrogen generation assembly 140) via communication linkages 164. For example, control assembly 162 may include any suitable structure configured to select a flowrate from the plurality of flowrates of  
10 pump 150 based on the detected pressure in the feed conduit, and/or to operate the pump at the selected flowrate. Communication linkages 164 may be any suitable wired and/or wireless mechanism for one- or two-way communication between the corresponding devices, such as input signals, command signals, measured parameters, etc.

15 Control assembly 162 may, for example, include at least one processor 170, as shown in Fig. 4. The processor may communicate with sensor assembly 160 and pump 150 and/or other controlled-devices via communication linkages 148. Processor 170 may have any suitable form, such as a computerized device, software executing on a computer, an embedded processor, programmable logic controller, an analog device  
20 (with one or more resistors), and/or functionally equivalent devices. The control assembly may include any suitable software, hardware, and/or firmware. For example, control assembly 162 may include memory device(s) 172 in which preselected,

preprogrammed, and/or user-selected operating parameters may be stored. The memory device may include volatile portion(s), nonvolatile portion(s), and/or both.

In some embodiments, processor 170 may be in the form of a signal conditioner 174, which may include any suitable structure configured to condition one or more  
5 signals received from sensor assembly 160. The signal conditioner may amplify, filter, convert, invert, range match, isolate, and/or otherwise modify one or more signals received from the sensor assembly such that the conditioned signals are suitable for downstream components. For example, signal conditioner 174 may invert one or more  
10 signals received from sensor assembly 160. "Invert," as used herein, refers to one or more of the following: converting a signal with a characteristic having ascending values to a signal with the characteristic having descending values, converting a signal with a characteristic having descending values to a signal with the characteristic having ascending values, converting a signal with a characteristic having a high value to a signal with the characteristic having a low value (or having the highest value to the  
15 lowest value), and/or converting a signal with a characteristic having a low value to a signal with the characteristic having a high value (or having the lowest value to the highest value). Characteristics of the signals may include voltage, current, etc. One or more of the converted values may match and/or correspond to values from the original signal, such as converting the highest original value to the lowest original value and/or  
20 converting the lowest original value to the highest original value. Alternatively, one or more of the converted values may be different from the original values of the signals.

In some embodiments, control assembly 162 may include a user interface 176, as shown in Fig. 4. The user interface may include any suitable structure configured to

allow a user to monitor and/or interact with operation of processor 170. For example, user interface 176 may include a display region 178, a user input device 180, and/or a user-signaling device 182, as shown in Fig. 4. The display region may include a screen and/or other suitable display mechanism in which information is presented to the user.

5 For example, display region 178 may display current values measured by one or more sensors 166, current operating parameters of the hydrogen generation assembly, stored threshold values or ranges, previously measured values, and/or other information regarding the operation and/or performance of the hydrogen generation assembly.

User input device 180 may include any suitable structure configured to receive  
10 input from the user and send that input to processor 170. For example, the user input device may include rotary dials, switches, push-buttons, keypads, keyboards, a mouse, touch screens, etc. User input device 180 may, for example, enable a user to specify how signals from sensor assembly 160 will be conditioned, such as whether the signal will be inverted, what the range of values of the inverted signal should be, etc. User-  
15 signaling device 182 may include any suitable structure configured to alert a user when an acceptable threshold level has been exceeded. For example, the user-signaling device may include an alarm, lights, and/or other suitable mechanism(s) for alerting a user.

In some embodiments, control assembly 162 may be configured to only condition  
20 signals received from sensor assembly 160 via signal conditioner 168 without additional processing of the signal and/or sending a different signal. In other words, the signal(s) from sensor assembly 160 may be conditioned via signal conditioner 168 and the conditioned signals may be sent to pump 150 and/or other controlled device(s) via

communication linkages 164 to operate the pump and/or other controlled devices without additional processing by the control assembly and/or other assemblies.

The conditioned signal (such as an inverted signal) may be configured, for example, to select a flowrate for pump 150 from the plurality of flowrates. When the  
5 conditioned signal is configured to select a flowrate for the pump, the control assembly may be described as being configured to select the flowrate based on (or based solely on) the conditioned signal.

An example of controlling pump 150 with a conditioned signal is shown in graph  
184 in Fig. 5. Sensor assembly 160 may include feed sensor 168 that detects pressure  
10 and sends a detection signal 186 to control assembly 162 based on the detected pressure. The detection signal may be a voltage signal as shown in Fig. 5, a current signal, and/or other suitable signals that are proportional to the detected pressure. The detection signal(s) may be any suitable voltage(s) and/or current(s), such as 0-5 volts and/or 4-20 milliamperes (mA).

15 Control assembly 162 may condition (such as invert) the detection signal into a conditioned signal 188 such that the conditioned signal is configured to select one or more parameters (such as flowrate and/or speed) for pump 150 and/or other controlled devices. The conditioned signal(s) may be any suitable voltage(s) and/or current(s), such as 0-5 volts and/or 4-20 mA. The voltages and pressure shown in Fig. 5 are only  
20 one example of the various voltages and pressures that may be generated and/or detected by control system 152. In other words, control system 152 is not limited to operation in the voltages and pressures shown in that figure.

Another example of hydrogen generation assembly 20 is generally indicated at 190 in Fig. 6. Unless specifically excluded, hydrogen generation assembly 190 may include one or more components of one or more other hydrogen generation assemblies described in this disclosure. Hydrogen generation assembly 190 may include a feedstock delivery system or feed assembly 192 and a fuel processing assembly 194 configured to receive at least one feed stream from the feedstock delivery system and produce one or more product hydrogen stream(s), such as a hydrogen gas stream, from the feed stream(s).

The feedstock delivery system may include a feedstock tank or feed tank (and/or container) 196, a feed conduit 198, a pump 200, and a control system 202. The feed tank may contain feedstock for one or more feed streams of the fuel processing assembly. Feed conduit 198 may fluidly connect feed tank 196 with fuel processing assembly 194. The feed conduit may include a feed portion 204 and a bypass portion 206. The bypass portion may be configured to prevent overpressurization in hydrogen generation assembly 190. For example, bypass portion 206 may include a pressure relief valve 208.

Pump 200 may have any suitable structure configured to deliver one or more feed and/or fuel streams to the fuel processing assembly at a plurality of flowrates to fuel processing assembly 194 via, for example, feed conduit 198. For example, pump 200 may be a variable-speed pump (or a pump that includes a variable speed motor) that injects the feed and/or fuel streams into the fuel processing assembly under pressure. The pump may operate at a speed based on a control signal from the control system.

Control system 202 may include any suitable structure configured to control and/or operate pump 200 and/or other controlled devices of hydrogen generation assembly 190. For example, control system 202 may include at least one pressure transducer 210, a control assembly 212, and communication linkages 214. Pressure  
5 transducer 210 may be configured to detect pressure in feed conduit 198. Although pressure transducer 210 is shown to be adjacent to pump 200 and/or bypass portion 206, the pressure transducer may be positioned in any suitable portions along the feed portion.

Control assembly 212 may include a power supply assembly 216 and a signal  
10 conditioner assembly 218. The power supply assembly may include any suitable structure configured to provide suitable power to the signal conditioner assembly. For example, the power supply assembly may include one or more batteries, one or more solar panels, one or more connectors for connecting to a DC or AC power source, etc. In some embodiments, power supply assembly 216 may include a DC power supply,  
15 which may provide the same voltage as is required to operate pump 200 and/or pressure transducer 210.

Signal conditioner assembly 218 may include any suitable structure configured to condition one or more signals received from pressure transducer 210 such that one or more of the conditioned signals may be used to operate pump 200. For example, signal  
20 conditioner assembly 218 may invert the pressure signals (or transducer signals) received from the pressure transducer and relay the inverted signals via communication linkages 214 to pump 200. The inverted signals may be configured to select a speed and/or flowrate for pump 200 among the plurality of speeds and/or flowrates for the

pump. When the inverted signals are used to control the pump's speed, the signals may be referred to as "speed control signals."

An example of a purge assembly of the hydrogen generation assemblies described in the present disclosure is shown in Fig. 7 and is generally indicated at 220.

5 The purge assembly may include any suitable structure configured to purge one or more other portions of a hydrogen generation assembly. Purge assembly 220 may be configured to purge one or more gases from reactor(s), purifier(s), fuel processing assembly(ies), and/or other component(s) and/or device(s) of hydrogen generation assemblies of the present disclosure and/or other hydrogen generation assemblies. For  
10 example, purge assembly 220 may include a pressurized gas assembly 222, a purge conduit 224, and a valve assembly 226. Purge conduit 224 may be configured to fluidly connect the pressurized gas assembly and one or more other portions of the hydrogen generation assembly.

Pressurized gas assembly 222 may include any suitable structure configured to  
15 connect to and/or receive at least one gas supply assembly 228. For example, pressurized gas assembly 222 may include any suitable connectors, piping, valves, and/or other components configured to connect to and/or receive gas supply assembly 228. The gas supply assembly may include one or more containers of pressurized gas (such as one or more cartridges and/or cylinders) and/or one or more tanks of  
20 pressurized gas. The gas supply assembly may include any suitable pressurized gas configured to purge one or more other components of the hydrogen generation assemblies described in the present disclosure. For example, gas supply assembly may include compressed carbon dioxide or compressed nitrogen.

Purge conduit 224 may be configured to fluidly connect the pressurized gas assembly and one or more other portions of the hydrogen generation assembly, such as the fuel processing assembly. The purge conduit may include any suitable connectors, piping, valves, and/or other components to provide for the fluid connection between the  
5 above assemblies.

Valve assembly 226 may include any suitable structure configured to manage flow of the pressurized gas through purge conduit 224 from pressurized gas assembly 222 to one or more other portions of the hydrogen generation assembly. For example, valve assembly 226 may be configured to allow at least one pressurized gas to flow  
10 through the purge conduit from the pressurized gas assembly to one or more other portions of the hydrogen generation assembly and/or to prevent the at least one pressurized gas to flow through the purge conduit from the pressurized gas assembly to one or more other portions of the hydrogen generation assembly. The valve assembly may be configured to allow or prevent flow based on one or more detected variable(s),  
15 parameter(s) and/or triggering event(s). For example, the valve assembly may be configured to allow flow of at least one pressurized gas from the pressurized gas assembly to one or more other portions of the hydrogen generation assembly when power to one or more portions of the hydrogen generation assembly is interrupted.

In some embodiments, a control system 230 may control one or more valves of  
20 valve assembly 226. Control system 230 may also control one or more other components of the hydrogen generation assembly, or may be dedicated to controlling only purge assembly 220. In some embodiments, valve assembly 226 may be configured to manage flow in the purge conduit independent of control system 230

and/or any control system of the hydrogen generation assembly. In other words, valve assembly 226 may be configured to selectively allow and prevent flow without direction from control system 230 and/or any control system of the hydrogen generation assembly.

5           The purge assembly may be located within enclosure or shell 66, external to the shell, or partially within the shell and partially external the shell. In some embodiments, at least a portion of the fuel processing assembly may be contained within an enclosure and at least a portion of the purge assembly may be contained within the enclosure, as shown in Fig. 1.

10           Purge assembly 220 may be connected to any suitable other component(s) of the hydrogen generation assembly. For example, as shown in Fig. 2, purge assembly 220 may be connected to the feed conduit either upstream of heat exchange assembly 136 (such as shown via purge conduit 224), and/or downstream of the heat exchange assembly (such as shown via a purge conduit 225). In some embodiments, the feed  
15           conduit of the hydrogen generation assembly may include a check valve 232 to prevent backflow of the pressurized gas into the feedstock delivery system, such as when the pump does not prevent backflow. The pressurized gas from the purge assembly may exit the hydrogen generation assembly at any suitable portions, such as the burner and/or the product hydrogen line.

20           Another example of purge assembly 220 is shown in Fig. 8 and is generally indicated at 232. Purge assembly 232 may include a pressurized gas assembly 234, a purge conduit 236, and a valve assembly 238. The pressurized gas assembly may include any suitable structure configured to receive at least one pressurized gas

container 240 having at least one pressurized gas. Purge conduit 236 may include any suitable structure configured to fluidly connect pressurized gas assembly 234 and one or more other portions of the hydrogen generation assembly.

Valve assembly 238 may include any suitable structure configured to manage  
5 flow of the at least one pressurized gas through the purge conduit from the pressurized gas assembly to one or more other portions of the hydrogen generation assembly. For example, valve assembly 238 may include a manual valve 240 and a solenoid valve (or purge solenoid valve) 242, as shown in Fig. 8. The manual valve may be closed to isolate the pressurized gas assembly from one or more other portions of the hydrogen  
10 generation assembly, such as when installing or connecting a compressed or pressurized gas canister to the pressurized gas assembly. Manual valve 240 may then be opened to allow the solenoid valve to manage flow of the gas through the purge conduit from the pressurized gas assembly to one or more other portions of the hydrogen generation assembly. Manual valve 240 may sometimes be referred to as a  
15 “manual isolation valve.”

Solenoid valve 242 may include at least one solenoid or purge solenoid 244 and at one valve or purge valve 246. The valve may be configured to move among a plurality of positions, including between a closed position and an open position. In the closed position, the pressurized gas assembly is isolated from one or more other  
20 portions of the hydrogen generation assembly and the pressurized gas does not flow through the purge conduit from the pressurized gas assembly. In the open position, the pressurized gas assembly is in fluid communication with one or more other portions of the hydrogen generation assembly and pressurized gas is allowed to flow through the

purge conduit from the pressurized gas assembly. Solenoid 244 may be configured to move valve 226 between the open and closed positions based on one or more detected variable(s), parameter(s) and/or triggering event(s). Solenoid valve 242 may, for example, be configured to allow flow of at least one pressurized gas from the pressurized gas assembly to one or more other portions of the hydrogen generation assembly when power to the solenoid and/or one or more portions of the hydrogen generation assembly is interrupted, such as when power to the fuel processing assembly is interrupted.

For example, valve 246 may be configured to be in the open position without power to solenoid 244 (may also be referred to as “normally open”), such as via urging of one or more bias elements or springs (not shown). Additionally, valve 246 may be configured to be in the closed position with power to solenoid 244 (which may move the valve to the closed position against urging of the bias element(s)). Thus, a loss of electrical power to one or more portions of the hydrogen generation assembly (and/or a loss of electrical power to solenoid 244) may cause valve 246 to automatically move from the closed position to the open position. In other words, valve 246 of solenoid valve 242 may be configured to be in the closed position when there is power to the solenoid and/or one or more portions of the hydrogen generation assembly (such as the fuel processing assembly), and may automatically move to the open position when power to the solenoid and/or one or more portions of the hydrogen generation assembly is interrupted.

In some embodiments, solenoid valve 242 may be controlled by a control system 248. For example, control system 248 may be configured to send a control signal to

solenoid 244 and the solenoid may be configured to move valve 246 to the closed position when the control signal is received. Additionally, valve 246 may be configured to automatically move to the open position when the solenoid does not receive a control signal from the control system. Control system 248 may control one or more other components of the hydrogen generation assembly or may be separate from any control system. The solenoid valve may, in some embodiments, be controlled by both the control system and whether power is supplied to the solenoid.

In some embodiments, purge assembly 220 may include a flow-restriction orifice 250, which may be configured to reduce or limit flow rate of the pressurized gas discharged from the pressurized gas assembly. For example, when the pressurized gas is nitrogen, the flow-restriction orifice may reduce or limit flow rate of the nitrogen gas to avoid overpressure in one or more other components of the hydrogen generation assembly, such as in the reformer and/or purifier. However, when the pressurized gas is liquefied compressed gas, such as carbon dioxide, the purge assembly may not include the flow-restriction orifice.

The purge assemblies of the present disclosure may be used as part of (or in) any suitable hydrogen generation assembly, such as a hydrogen generation assembly with a reformer but without a hydrogen purifier, a hydrogen generation assembly with a hydrogen purifier but without a reformer, a hydrogen generation assembly with a methanol/water reformer, a natural gas reformer, a LPG reformer, etc.

Another example of hydrogen generation assembly 20 is generally indicated at 252 in Fig. 9. Unless specifically excluded, hydrogen generation assembly 252 may include one or more components of one or more other hydrogen generation assemblies

described in this disclosure. Hydrogen generation assembly 252 may include an enclosure or shell 254, a hydrogen-producing region 256, a heating assembly 258, and an exhaust management assembly 260. The enclosure or shell may include any suitable structure configured to at least partially contain one or more other components  
5 of hydrogen generation assembly 252 and/or provide insulation (such as thermal insulation) for those component(s). The enclosure may define an insulated zone or insulated hot zone 261 for the components within the enclosure. Enclosure 254 may include at least one exhaust port 262 configured to exhaust gases within the enclosure to the environment and/or to an exhaust collection system.

10 Hydrogen-producing region 256 may be partially or fully contained within the enclosure. The hydrogen-producing region may receive one or more feed streams 264 and produce an output stream 266 containing hydrogen gas via any suitable hydrogen-producing mechanism(s), such as steam reforming, autothermal reforming, etc. The output stream may include hydrogen gas as at least a majority component and may  
15 include additional gases. When hydrogen generation assembly 252 is a steam reforming hydrogen generation assembly, then the hydrogen-producing region may be referred to as being configured to produce, via a steam reforming reaction, a reformat stream 266.

In some embodiments, hydrogen generation assembly 252 may include a  
20 purification region 268, which may include any suitable structure configured to produce at least one hydrogen-rich (or permeate) stream 270 from output (or reformat) stream 266 and at least one byproduct stream 272 (which may contain no or some hydrogen gas). For example, the purification region may include one or more hydrogen-selective

membranes 274. The hydrogen-selective membrane(s) may be configured to produce at least part of the permeate stream from the portion of the reformat stream that passes through the hydrogen-selective membrane(s), and to produce at least part of the byproduct stream from the portion of the reformat stream that does not pass through the hydrogen-selective membrane(s). In some embodiments, hydrogen generation assembly 252 may include a vaporization region 276, which may include any suitable structure configured to vaporize the feed stream(s) containing one or more liquid(s).

Heating assembly 258 may be configured to receive at least one air stream 278 and at least one fuel stream 280 and to combust the fuel stream(s) within a combustion region 282 contained within enclosure 254. Fuel stream 280 may be produced from the hydrogen-producing region (and/or the purification region), and/or may be produced independent of the hydrogen generation assembly. The combustion of the fuel stream(s) may produce one or more heated exhaust streams 284. The heated exhaust stream(s) may heat, for example, hydrogen-producing region 256, such as to at least a minimum hydrogen-producing temperature. Additionally, the heated exhaust stream(s) may heat vaporization region 276, such as to at least a minimum vaporization temperature.

Exhaust management assembly 260 may include any suitable structure configured to manage exhaust streams in enclosure 254, such as heated exhaust streams 284. For example, the exhaust management assembly may include a sensor assembly 286, a damper assembly 288, and a control assembly 290, as shown in Fig. 9.

Sensor assembly 286 may include any suitable structure configured to detect and/or measure one or more suitable operating variables and/or parameters in the hydrogen generation assembly and/or generate one or more signals based on the detected and/or measured operating variable(s) and/or parameter(s). For example, the  
5 sensor assembly may detect mass, volume, flow, temperature, electrical current, pressure, refractive index, thermal conductivity, density, viscosity, optical absorbance, electrical conductivity, and/or other suitable variable(s), and/or parameter(s). In some embodiments, the sensor assembly may detect one or more triggering events.

For example, sensor assembly 286 may include one or more sensors 292  
10 configured to detect pressure, temperature, flowrate, volume, and/or other parameters in any suitable portion(s) of the hydrogen generation assembly. Sensors 292 may, for example, include at least one hydrogen-producing region sensor 294 configured to detect one or more suitable operating variables, parameters, and/or triggering events in hydrogen-producing region 256. The hydrogen-producing region sensor may be  
15 configured to detect, for example, temperature in the hydrogen-producing region and/or generate one or more signals based on the detected temperature in the hydrogen-producing region.

Additionally, sensors 292 may include at least one purification region sensor 296 configured to detect one or more suitable operating variables, parameters, and/or  
20 triggering events in purification region 268. The purification region sensor may be configured to detect, for example, temperature in the purification region and/or generate one or more signals based on the detected temperature in the purification region.

Damper assembly 288 may include any suitable structure configured to manage flow, such as the flow of exhaust gases (or heated exhaust stream(s) 284), through exhaust port 262. For example, damper assembly 288 may include at least one damper 298 and at least one actuator 300. The damper may be moveably connected to exhaust  
5 port 262. For example, damper 298 may be slidably, pivotably, and/or rotatably connected to the exhaust port.

Additionally, the damper may be configured to move among a plurality of positions. Those positions may include, for example, a fully open position 302, a closed position 304, and a plurality of intermediate open positions 306 between the fully open  
10 and closed positions, as shown in Figs. 10-12. In the fully open position, damper 298 may allow one or more exhaust streams 307 (such as heated exhaust stream(s) 284 and/or other exhaust gases in the enclosure) to flow through exhaust port 262. In the closed position, damper 298 may block the exhaust port and prevent exhaust stream(s) from flowing through the exhaust port. The intermediate open positions may allow the  
15 exhaust stream(s) to flow through exhaust port 262 at slower rate(s) than when the damper is in the fully open position. During operation, the temperature in the hydrogen-producing region may decrease when the exhaust stream(s) are restricted by the damper.

Damper 298 may include any suitable structure. For example, damper 298 may  
20 be a gate-type damper with one or more plates that slide across the exhaust port, such as shown in Figs. 10-12. Additionally, damper 298 may be a flapper-type damper, such as shown in Fig. 9. The flapper-type damper may, for example, include full circle or half-circle inserts that pivot to open or close the exhaust. Actuator 300 may include any

suitable structure configured to move damper 298 among the plurality of positions. In some embodiments, the actuator may move the damper incrementally between the fully open and closed positions. Although damper assembly 288 is shown to include a single damper and a single actuator, the damper assembly may include two or more dampers  
5 and/or two or more actuators.

Control assembly 290 may include any suitable structure configured to control damper assembly 288 based, at least in part, on input(s) from sensor assembly 286, such as based, at least in part, on detected and/or measured operating variable(s) and/or parameter(s) by the sensor assembly. Control assembly 290 may receive  
10 input(s) only from sensor assembly 286 or the control assembly may receive input(s) from other sensor assemblies of the hydrogen generation assembly. Control assembly 290 may control only damper assembly, or the control assembly may control one or more other components of the hydrogen generation assembly.

Control assembly 290 may, for example, be configured to move damper 298,  
15 such as via actuator 300, between the fully open and closed positions based, at least in part, on the detected temperature in the hydrogen-producing region and/or the purification region. When control assembly 290 receives inputs from two or more sensors, the control assembly may select the input with a higher value, may select the input with a lower value, may calculate an average of the input values, may calculate a  
20 median of the input values, and/or perform other suitable calculation(s). For example, control assembly 290 may be configured to move the damper toward (or incrementally toward) the closed position when detected temperature in the hydrogen-producing and/or purification regions are above a predetermined maximum temperature, and/or to

move the damper toward (or incrementally toward) the fully open position when the detected temperature in the hydrogen-producing and/or purification regions are below a predetermined minimum temperature. The predetermined maximum and minimum temperatures may be any suitable maximum and minimum temperatures. For example, the maximum and minimum temperatures may be set based on a desired range of temperatures for operating the vaporization, hydrogen-producing, and/or purification regions.

Another example of hydrogen generation assembly 20 is generally indicated at 308 in Fig. 13. Unless specifically excluded, hydrogen generation assembly 308 may include one or more components of one or more other hydrogen generation assemblies described in this disclosure. The hydrogen generation assembly may provide or supply hydrogen to one or more hydrogen consuming devices 310, such as a fuel cell, hydrogen furnace, etc. Hydrogen generation assembly 308 may, for example, include a fuel processing assembly 312 and a product hydrogen management system 314.

Fuel processing assembly 312 may include any suitable structure configured to generate one or more product hydrogen streams 316 (such as one or more hydrogen gas streams) from one or more feed streams 318 via one or more suitable mechanisms, such as steam reforming, autothermal reforming, electrolysis, thermolysis, partial oxidation, plasma reforming, photocatalytic water splitting, sulfur-iodine cycle, etc. For example, fuel processing assembly 312 may include one or more hydrogen generator reactors 320, such as reformer(s), electrolyzer(s), etc. Feed stream(s) 318 may be delivered to the fuel processing assembly via one or more feed conduits 317 from one or more feedstock delivery systems (not shown).

Fuel processing assembly 312 may be configured to be operable among a plurality of modes, such as a run mode and a standby mode. In the run mode, the fuel processing assembly may produce or generate the product hydrogen stream(s) from the feed stream(s). For example, in the run mode, the feedstock delivery system may deliver the feed stream to the fuel processing assembly and/or may perform other operation(s). Additionally, in the run mode, the fuel processing assembly may receive the feed stream, may combust the fuel stream via the heating assembly, may vaporize the feed stream via the vaporization region, may generate the output stream via the hydrogen producing region, may generate the product hydrogen stream and the byproduct stream via the purification region, and/or may perform other operations.

In the standby mode, fuel processing assembly 312 may not produce the product hydrogen stream(s) from the feed stream(s). For example, in the standby mode, the feedstock delivery system may not deliver the feed stream to the fuel processing assembly and/or may not perform other operation(s). Additionally, in the standby mode, the fuel processing assembly may not receive the feed stream, may not combust the fuel stream via the heating assembly, may not vaporize the feed stream via the vaporization region, may not generate the output stream via the hydrogen producing region, may not generate the product hydrogen stream and the byproduct stream via the purification region, and/or may not perform other operations. The standby mode may include when the fuel processing assembly is powered down or when there is no power to the fuel processing assembly.

In some embodiments, the plurality of modes may include one or more reduced output modes. For example, fuel processing assembly 312 may produce or generate

product hydrogen stream(s) 316 at a first output rate when in the run mode (such as at a maximum output rate or normal output rate), and produce or generate the product hydrogen stream(s) at second, third, fourth, or more rates that are lower (or higher) than the first rate when in the reduced output mode (such as at a minimum output rate).

- 5           Product hydrogen management system 314 may include any suitable structure configured to manage product hydrogen generated by fuel processing assembly 312. Additionally, the product hydrogen management system may include any suitable structure configured to interact with fuel processing assembly 312 to maintain any suitable amount of product hydrogen available for hydrogen consuming device(s) 310.
- 10          For example, product hydrogen management system 314 may include a product conduit 322, a buffer tank 324, a buffer tank conduit 325, a sensor assembly 326, and a control assembly 328.

Product conduit 322 may be configured to fluidly connect fuel processing assembly 312 with buffer tank 324. Buffer tank 324 may be configured to receive

15          product hydrogen stream 316 via product conduit 322, to retain a predetermined amount or volume of the product hydrogen stream, and/or to provide the product hydrogen stream to one or more hydrogen consuming devices 310. In some embodiments, the buffer tank may be a lower-pressure buffer tank. The buffer tank may be any suitable size based on one or more factors, such as expected or actual

20          hydrogen consumption by the hydrogen consuming device(s), cycling characteristics of the hydrogen generator reactor, fuel processing assembly, etc.

In some embodiments, buffer tank 324 may be sized to provide enough hydrogen for a minimum amount of time of operation of the hydrogen consuming device(s) and/or

for a minimum amount of time of operation for the fuel processing assembly, such as a minimum amount of time of operation for the vaporization region, hydrogen-producing region, and/or purification region. For example, the buffer tank may be sized for two, five, ten, or more minutes of operation of the fuel processing assembly. Buffer tank  
5 conduit 325 may be configured to fluidly connect buffer tank 324 with hydrogen consuming device(s) 310.

Sensor assembly 326 may include any suitable structure configured to detect and/or measure one or more suitable operating variables and/or parameters in the buffer tank and/or generate one or more signals based on the detected and/or  
10 measured operating variable(s) and/or parameter(s). For example, the sensor assembly may detect mass, volume, flow, temperature, electrical current, pressure, refractive index, thermal conductivity, density, viscosity, optical absorbance, electrical conductivity, and/or other suitable variable(s), and/or parameter(s). In some embodiments, the sensor assembly may detect one or more triggering events.

15 For example, sensor assembly 326 may include one or more sensors 330 configured to detect pressure, temperature, flowrate, volume, and/or other parameters. Sensors 330 may, for example, include at least one buffer tank sensor 332 configured to detect one or more suitable operating variables, parameters, and/or triggering events in the buffer tank. The buffer tank sensor may be configured to detect, for example,  
20 pressure in the buffer tank and/or generate one or more signals based on the detected pressure. For example, unless product hydrogen is being withdrawn from the buffer tank at a flow rate that is equal to, or greater than, the incoming flow rate into the buffer tank,

the pressure of the buffer tank may increase and the tank sensor may detect the increase of pressure in the buffer tank.

Control assembly 328 may include any suitable structure configured to control fuel processing assembly 312 based, at least in part, on input(s) from sensor assembly 326, such as based, at least in part, on detected and/or measured operating variable(s) and/or parameter(s) by the sensor assembly. Control assembly 328 may receive input(s) only from sensor assembly 326 or the control assembly may receive input(s) from other sensor assemblies of the hydrogen generation assembly. Control assembly 328 may control only the fuel processing assembly, or the control assembly may control one or more other components of the hydrogen generation assembly. The control assembly may communicate with the sensor assembly, the fuel processing assembly, and/or a product valve assembly (further described below) via communication linkages 333. Communication linkages 333 may be any suitable wired and/or wireless mechanism for one- or two-way communication between the corresponding devices, such as input signals, command signals, measured parameters, etc.

Control assembly 328 may, for example, be configured to operate fuel processing assembly 312 between the run and standby modes based, at least in part, on the detected pressure in buffer tank 324. For example, control assembly 328 may be configured to operate the fuel processing assembly in the standby mode when the detected pressure in the buffer tank is above a predetermined maximum pressure, and/or to operate the fuel processing assembly in the run mode when the detected pressure in the buffer tank is below a predetermined minimum pressure.

The predetermined maximum and minimum pressures may be any suitable maximum and minimum pressures. Those predetermined pressures may be independently set, or set without regard to other predetermined pressure(s) and/or other predetermined variable(s). For example, the predetermined maximum pressure may be  
5 set based on the operating pressure range of the fuel processing assembly, such as to prevent overpressure in the fuel processing assembly because of back pressure from the product hydrogen management system. Additionally, the predetermined minimum pressure may be set based on the pressure required by the hydrogen consuming device(s). Alternatively, control assembly 328 may operate the fuel processing  
10 assembly to operate in the run mode within a predetermined range of pressure differentials (such as between the fuel processing assembly and the buffer tank and/or between the buffer tank and the hydrogen consuming device(s)), and in the standby mode when outside the predetermined range of pressure differentials.

In some embodiments, product hydrogen management system 314 may include  
15 a product valve assembly 334, which may include any suitable structure configured to manage and/or direct flow in product conduit 322. For example, the product valve assembly may allow the product hydrogen stream to flow from the fuel processing assembly to the buffer tank, as indicated at 335. Additionally, product valve assembly 334 may be configured to vent product hydrogen stream 316 from fuel processing  
20 assembly 312, as indicated at 337. The vented product hydrogen stream may be discharged to atmosphere and/or to a vented product hydrogen management system (not shown).

Product valve assembly 334 may, for example, include one or more valves 336 that are configured to operate between a flow position in which the product hydrogen stream from the fuel processing assembly flows through the product conduit and into the buffer tank, and a vent position in which the product hydrogen stream from the fuel  
5 processing assembly is vented. Valve(s) 336 may be positioned along any suitable portion(s) of the product conduit prior to the buffer tank.

Control assembly 328 may be configured to operate the product valve assembly based on, for example, input(s) from sensor assembly. For example, the control assembly may direct or control the product valve assembly (and/or valve(s) 336) to vent  
10 the product hydrogen stream from the fuel processing assembly when the fuel processing assembly is in the standby mode. Additionally, control assembly 328 may direct or control product valve assembly 334 (and/or valve(s) 336) to allow the product hydrogen stream to flow from the fuel processing assembly to the buffer tank when fuel processing assembly 312 is in the run mode and/or reduced output mode(s).

15 Another example of hydrogen generation assembly 20 is generally indicated at 338 in Fig. 14. Unless specifically excluded, hydrogen generation assembly 338 may include one or more components of one or more other hydrogen generation assemblies described in this disclosure. The hydrogen generation assembly may provide or supply hydrogen to one or more hydrogen consuming devices 340, such as a fuel cell,  
20 hydrogen furnace, etc. Hydrogen generation assembly 338 may, for example, include a fuel processing assembly 342 and a product hydrogen management system 344. Fuel processing assembly 342 may include any suitable structure configured to generate one

or more product hydrogen streams 346 (such as one or more hydrogen gas streams) from one or more feed streams 348 via one or more suitable mechanisms.

Product hydrogen management system 344 may include any suitable structure configured to manage product hydrogen generated by fuel processing assembly 342.

5 Additionally, the product hydrogen management system may include any suitable structure configured to interact with fuel processing assembly 342 to maintain any suitable amount of product hydrogen available for hydrogen consuming device(s) 340. For example, product hydrogen management system 344 may include a product conduit 349, a buffer tank 352, a buffer tank conduit 353, a buffer tank sensor assembly 354, a  
10 product valve assembly 355, and a control assembly 356.

Product conduit 349 may be configured to fluidly connect fuel processing assembly 342 with buffer tank 352. The product conduit may include any suitable number of valves, such as check valve(s) (such as check valve 350), control valve(s), and/or other suitable valves. Check valve 350 may prevent backflow from the buffer  
15 tank toward the fuel processing assembly. The check valve may open at any suitable pressures, such as 1 psi or less. Buffer tank 352 may be configured to receive product hydrogen stream 346 via product conduit 349, to retain a predetermined amount or volume of the product hydrogen stream, and/or to provide the product hydrogen stream to one or more hydrogen consuming devices 340.

20 Buffer tank conduit 353 may be configured to fluidly connect buffer tank 352 and hydrogen consuming device(s) 340. The buffer tank conduit may include any suitable number of valves, such as check valve(s), control valve(s), and/or other suitable valve(s). For example, the buffer tank conduit may include one or more control valves

351. Control valve 351 may allow isolation of the buffer tank and/or other components of the hydrogen generation assembly. The control valve may, for example, be controlled by control assembly 356 and/or other control assembly(ies).

Tank sensor assembly 354 may include any suitable structure configured to  
5 detect and/or measure one or more suitable operating variables and/or parameters in the buffer tank and/or generate one or more signals based on the detected and/or measured operating variable(s) and/or parameter(s). For example, the buffer tank sensor assembly may detect mass, volume, flow, temperature, electrical current, pressure, refractive index, thermal conductivity, density, viscosity, optical absorbance,  
10 electrical conductivity, and/or other suitable variable(s), and/or parameter(s). In some embodiments, the buffer tank sensor assembly may detect one or more triggering events. For example, buffer tank sensor assembly 354 may include one or more tank sensors 358 configured to detect pressure, temperature, flowrate, volume, and/or other parameters. Buffer tank sensors 358 may, for example, be configured to detect  
15 pressure in the buffer tank and/or generate one or more signals based on the detected pressure.

Product valve assembly 355 may include any suitable structure configured to manage and/or direct flow in product conduit 349. For example, the product valve assembly may allow the product hydrogen stream to flow from the fuel processing  
20 assembly to the buffer tank, as indicated at 359. Additionally, product valve assembly 355 may be configured to vent product hydrogen stream 346 from fuel processing assembly 342, as indicated at 361. The vented product hydrogen stream may be discharged to atmosphere and/or to a vented product hydrogen management system

(not shown) including discharging vented product hydrogen back to the fuel processing assembly.

Product valve assembly 355 may, for example, include a three-way solenoid valve 360. The three-way solenoid valve may include a solenoid 362 and a three-way valve 364. The three-way valve may be configured to move between a plurality of positions. For example, three-way valve 364 may be configured to move between a flow position 363 and a vent position 365, as shown in Figs. 15-16. In the flow position, the product hydrogen stream is allowed to flow from the fuel processing assembly to the buffer tank, as indicated at 359. In the vent position, the product hydrogen stream from the fuel processing assembly is vented, as indicated at 361. Additionally, the three-way valve may be configured to isolate the buffer tank from the product hydrogen stream when the valve is in the vent position. Solenoid 362 may be configured to move valve 364 between the flow and vent positions based on input(s) received from control assembly 356 and/or other control assembly(ies).

Control assembly 356 may include any suitable structure configured to control fuel processing assembly 342 and/or product valve assembly 355 based, at least in part, on input(s) from buffer tank sensor assembly 354, such as based, at least in part, on detected and/or measured operating variable(s) and/or parameter(s) by the buffer tank sensor assembly. Control assembly 356 may receive input(s) only from buffer tank sensor assembly 354 and/or the control assembly may receive input(s) from other sensor assemblies of the hydrogen generation assembly. Additionally, control assembly 356 may control only the fuel processing assembly, only the product valve assembly, only both the fuel processing assembly and the product valve assembly, or the fuel

processing assembly, product valve assembly and/or one or more other components of the hydrogen generation assembly. Control assembly 356 may communicate with the fuel processing assembly, the buffer tank sensor assembly, and the product valve assembly via communication linkages 357. Communication linkages 357 may be any  
5 suitable wired and/or wireless mechanism for one- or two-way communication between the corresponding devices, such as input signals, command signals, measured parameters, etc.

Control assembly 356 may, for example, be configured to operate fuel processing assembly 342 among or between the run and standby modes (and/or  
10 reduced output mode(s)) based, at least in part, on the detected pressure in buffer tank 352. For example, control assembly 356 may be configured to operate the fuel processing assembly in the standby mode when the detected pressure in the buffer tank is above a predetermined maximum pressure, to operate the fuel processing assembly in one or more reduced output mode(s) when the detected pressure in the buffer tank is  
15 below a predetermined maximum pressure and/or above a predetermined operating pressure, and/or to operate the fuel processing assembly in the run mode when the detected pressure in the buffer tank is below a predetermined operating pressure and/or predetermined minimum pressure. The predetermined maximum and minimum pressures and/or predetermined operating pressure(s) may be any suitable pressures.  
20 For example, the one or more of the above pressures may be independently set based on a desired range of pressures for the fuel processing assembly, product hydrogen in the buffer tank, and/or the pressure requirements of the hydrogen consuming device(s). Alternatively, control assembly 356 may operate the fuel processing assembly to

operate in the run mode within a predetermined range of pressure differentials (such as between the fuel processing assembly and the buffer tank), and in the reduced output and/or standby mode when outside the predetermined range of pressure differentials.

Additionally, control assembly 356 may be configured to operate the product  
5 valve assembly based on, for example, input(s) from sensor assembly. For example, the control assembly may direct or control solenoid 362 to move three-way valve 364 to the vent position when the fuel processing assembly is in the standby mode. Additionally, control assembly 356 may direct or control the solenoid to move three-way valve 364 to the flow position when fuel processing assembly 342 is in the run mode.

10 Control assembly 356 may, for example, include a controller 366, a switching device 368, and a power supply 370. Controller 366 may have any suitable form, such as a computerized device, software executing on a computer, an embedded processor, programmable logic controller, an analog device, and/or functionally equivalent devices. Additionally, the controller may include any suitable software, hardware, and/or  
15 firmware.

Switching device 368 may include any suitable structure configured to allow controller 366 to control solenoid 362. For example, the switching device may include a solid-state relay 372. The solid-state relay may allow controller 366 to control solenoid 362 via power supply 370. For example, when solenoid 362 is controlled with 24 volts,  
20 the solid-state relay may allow controller 366 to use a voltage signal less than 24 volts (such as 5 volts) to control solenoid 362. Power supply 370 may include any suitable structure configured to provide power sufficient to control solenoid 362. For example, power supply 370 may include one or more batteries, one or more solar panels, etc. In

some embodiments, the power supply may include one or more electrical outlet connectors and one or more rectifiers (not shown). Although the solenoid and controller are described to operate at certain voltages, the solenoid and controller may operate at any suitable voltages.

5           Another example of hydrogen generation assembly 20 is generally indicated at 374 in Fig. 17. Unless specifically excluded, hydrogen generation assembly 374 may include one or more components of one or more other hydrogen generation assemblies described in this disclosure. The hydrogen generation assembly may provide or supply hydrogen to one or more hydrogen consuming devices 376, such as a fuel cell,  
10   hydrogen furnace, etc. Hydrogen generation assembly 374 may, for example, include a fuel processing assembly 378 and a product hydrogen management system 380. Fuel processing assembly 378 may include any suitable structure configured to generate one or more product hydrogen streams 382 (such as one or more hydrogen gas streams) from one or more feed streams 384 via one or more suitable mechanisms.

15           Product hydrogen management system 380 may include any suitable structure configured to manage product hydrogen generated by fuel processing assembly 382 and/or interact with fuel processing assembly 382 to maintain any suitable amount of product hydrogen available for hydrogen consuming device(s) 376. For example, product hydrogen management system 380 may include a product conduit 386, a buffer  
20   tank 388, a buffer tank conduit 389, a tank sensor assembly 390, a product valve assembly 392, and a control assembly 394.

Product conduit 386 may be configured to fluidly connect fuel processing assembly 378 with buffer tank 388. The product conduit may include a flow portion or

leg 395 and a vent portion or leg 396. Additionally, product conduit 386 may include any suitable number of valves, such as check valve(s) (such as check valve 397), control valve(s), and/or other suitable valve(s). Buffer tank 388 may be configured to receive product hydrogen stream 382 via product conduit 386, to retain predetermined  
5 amount(s) or volume(s) of the product hydrogen stream, and/or to provide the product hydrogen stream to one or more hydrogen consuming devices 376.

Buffer tank conduit 389 may be configured to fluidly connect buffer tank 388 with hydrogen consuming device(s) 376. The buffer tank conduit may include any suitable number of valves, such as check valve(s), control valve(s), and/or other suitable  
10 valve(s). For example, the buffer tank conduit may include one or more control valves 398. Control valve 398 may allow isolation of the buffer tank and/or other components of the hydrogen generation assembly. The control valve may, for example, be controlled by control assembly 394 and/or other control assembly(ies).

Tank sensor assembly 390 may include any suitable structure configured to  
15 detect and/or measure one or more suitable operating variables and/or parameters in the buffer tank and/or generate one or more signals based on the detected and/or measured operating variable(s) and/or parameter(s). For example, the tank sensor assembly may detect mass, volume, flow, temperature, electrical current, pressure, refractive index, thermal conductivity, density, viscosity, optical absorbance, electrical  
20 conductivity, and/or other suitable variable(s), and/or parameter(s). In some embodiments, the tank sensor assembly may detect one or more triggering events. For example, tank sensor assembly 390 may include one or more tank sensors 400 configured to detect pressure, temperature, flowrate, volume, and/or other parameters.

Tank sensors 400 may, for example, be configured to detect pressure in the buffer tank and/or generate one or more signals based on the detected pressure.

Product valve assembly 392 may include any suitable structure configured to manage and/or direct flow in product conduit 386. For example, the product valve assembly may allow the product hydrogen stream to flow from the fuel processing assembly to the buffer tank (as indicated at 401), and/or vent product hydrogen stream 382 from fuel processing assembly 378 (as indicated at 403). The vented product hydrogen stream may be discharged to atmosphere and/or to a vented product hydrogen management system (not shown).

Product valve assembly 392 may, for example, include a first solenoid valve 402 and a second solenoid valve 404. The first solenoid valve may include a first solenoid 406 and a first valve 408, while the second solenoid valve may include a second solenoid 410 and a second valve 412. As shown in Figs. 18-19, the first valve may be configured to move between a plurality of positions, including a first open position 407 and a first closed position 409. Additionally, the second valve may be configured to move between a plurality of positions, including a second open position 411 and a second closed position 413.

When the first valve is in the open position, the product hydrogen stream is allowed to flow from the fuel processing assembly to the buffer tank. In contrast, when the first valve is in the closed position, buffer tank is isolated from the product hydrogen stream from the fuel processing assembly (or the product hydrogen stream from the fuel processing assembly is not allowed to flow to the buffer tank). When the second valve is in the open position, the product hydrogen stream from the fuel processing assembly is

vented. In contrast, when the second valve is in the closed position, the product hydrogen stream from the fuel processing assembly is not vented.

First solenoid 406 may be configured to move first valve 408 between the open and closed positions based on input(s) received from control assembly 394.

5 Additionally, second solenoid 410 may be configured to move second valve 412 between the open and closed position based on input(s) received from the control assembly.

Control assembly 394 may include any suitable structure configured to control fuel processing assembly 378 and/or product valve assembly 392 based, at least in  
10 part, on input(s) from buffer tank sensor assembly 390, such as based, at least in part, on detected and/or measured operating variable(s) and/or parameter(s) by the buffer tank sensor assembly. Control assembly 394 may receive input(s) only from buffer tank sensor assembly 390 and/or the control assembly may receive input(s) from other sensor assemblies of the hydrogen generation assembly. Additionally, control assembly  
15 394 may control only the fuel processing assembly, only the product valve assembly, only both the fuel processing assembly and the product valve assembly, or the fuel processing assembly, product valve assembly and/or one or more other components of the hydrogen generation assembly. Control assembly 394 may communicate with the fuel processing assembly, the buffer tank sensor assembly, and/or the product valve  
20 assembly via communication linkages 393. Communication linkages 393 may be any suitable wired and/or wireless mechanism for one- or two-way communication between the corresponding devices, such as input signals, command signals, measured parameters, etc.

Control assembly 394 may, for example, be configured to operate fuel processing assembly 378 between the run and standby modes (and/or reduced output mode(s)) based, at least in part, on the detected pressure in buffer tank 388. For example, control assembly 394 may be configured to operate the fuel processing  
5 assembly in the standby mode when the detected pressure in the buffer tank is above a predetermined maximum pressure, to operate the fuel processing assembly in one or more reduced output mode(s) when the detected pressure in the buffer tank is below a predetermined maximum pressure and/or above a predetermined operating pressure, and/or to operate the fuel processing assembly in the run mode when the detected  
10 pressure in the buffer tank is below a predetermined operating pressure and/or predetermined minimum pressure. The predetermined maximum and minimum pressures and/or predetermined operating pressure(s) may be any suitable pressures. For example, the one or more of the above pressures may be independently set based on a desired range of pressures for the fuel processing assembly, the product hydrogen  
15 in the buffer tank, and/or the pressure requirements of the hydrogen consuming device(s). Alternatively, control assembly 394 may operate the fuel processing assembly to operate in the run mode within a predetermined range of pressure differentials (such as between the fuel processing assembly and the buffer tank and/or between the buffer tank and the hydrogen consuming device(s)), and in the reduced  
20 output and/or standby mode(s) when outside the predetermined range of pressure differentials.

Additionally, control assembly 394 may be configured to operate the product valve assembly based on, for example, input(s) from sensor assembly. For example,

the control assembly may direct or control the first and/or second solenoids to move the first valve in the closed position and/or the second valve in the open position when the fuel processing assembly is in the standby mode. Additionally, control assembly 394 may direct or control the first and/or second solenoids to move the first valve in the open  
5 position and/or the second valve in the closed position when fuel processing assembly 378 is in the run mode and/or reduced output mode(s).

Control assembly 394 may, for example, include a controller 414, a switching device 416, and a power supply 418. Controller 414 may have any suitable form, such as a computerized device, software executing on a computer, an embedded processor,  
10 programmable logic controller, an analog device, and/or functionally equivalent devices. Additionally, the controller may include any suitable software, hardware, and/or firmware.

Switching device 416 may include any suitable structure configured to allow controller 414 to control the first and/or second solenoids. For example, the switching  
15 device may include a solid-state relay 420. Power supply 418 may include any suitable structure configured to provide power sufficient to control the first and/or second solenoids.

Hydrogen generation assemblies of the present disclosure may include one or more of the following:

- 20     ○ A feed assembly configured to deliver a feed stream to a fuel processing assembly.
- A feed tank configured to contain feedstock for a feed stream.
- A feed conduit fluidly connecting a feed tank and a fuel processing assembly.

- A pump configured to deliver a feed stream at a plurality of flowrates to a fuel processing assembly via a feed conduit.
- A feed sensor assembly configured to detect pressure in a feed conduit downstream from a pump.
- 5      ○ A feed sensor assembly configured to generate a signal based on detected pressure.
- A pump controller configured to select a flowrate from a plurality of flowrates based on detected pressure.
- A pump controller configured to operate a pump at a selected flowrate.
- 10     ○ A pump controller configured to select a flowrate for a pump based solely on detected pressure.
- A pump controller configured to condition a signal received from a sensor assembly.
- A pump controller configured to invert a signal received from a feed sensor assembly.
- 15     ○ A pump controller configured to select a flowrate based on a conditioned signal.
- A pump controller configured to select a flowrate based on an inverted signal.
- A fuel processing assembly configured to receive a feed stream.
- A fuel processing assembly configured to produce a product hydrogen stream
- 20     from a feed stream.
- A fuel processing assembly configured to be operable among a plurality of modes.

- A fuel processing assembly configured to be operable among a run mode in which the fuel processing assembly produces a product hydrogen stream from a feed stream, and a standby mode in which the fuel processing assembly does not produce the product hydrogen stream from the feed stream.
- 5   ○ A purge assembly.
- A pressurized gas assembly configured to receive at least one container of pressurized gas that is configured to purge a fuel processing assembly.
- A purge conduit configured to fluidly connect a pressurized gas assembly and a fuel processing assembly.
- 10   ○ A purge valve assembly configured to allow at least one pressurized gas to flow through a purge conduit from a pressurized gas assembly to a hydrogen generation assembly when power to the hydrogen generation assembly is interrupted.
- A solenoid valve that moves between a closed position in which at least one  
15   pressurized gas does not flow through a purge conduit from a pressurized gas assembly, and an open position in which the at least one pressurized gas is allowed to flow through the purge conduit from the pressurized gas assembly.
- A solenoid valve that is in the closed position when there is power to a fuel processing assembly.
- 20   ○ A solenoid valve that automatically moves to an open position when power to a fuel processing assembly is interrupted.
- A solenoid valve configured to move to a closed position when the solenoid valve receives a control signal.

- A solenoid valve configured to automatically move to an open position when the solenoid valve does not receive a control signal.
- A control system configured to send a control signal to a solenoid valve.
- An enclosure containing at least a portion of a fuel processing assembly and at  
5 least a portion of a purge assembly.
- An enclosure having an exhaust port.
- A hydrogen-producing region contained within an enclosure.
- A hydrogen-producing region configured to produce, via a steam reforming reaction, a reformat stream from at least one feed stream.
- A purification region contained within an enclosure.
- A purification region including a hydrogen-selective membrane.
- A purification region configured to produce a permeate stream comprised of the  
10 portion of a reformat stream that passes through a hydrogen-selective membrane, and a byproduct stream comprised of the portion of the reformat stream that does not pass through the membrane.
- A reformer sensor assembly configured to detect temperature within a hydrogen-producing region.
- A reformer sensor assembly configured to detect temperature in the purification region.
- A heating assembly configured to receive at least one air stream and at least one  
20 fuel stream.
- A heating assembly configured to combust at least one fuel stream within a combustion region contained within an enclosure producing a heated exhaust

stream for heating at least a hydrogen-producing region to at least a minimum hydrogen-producing temperature.

- A damper moveably connected to an exhaust port.
- A damper configured to move among a plurality of positions.
- 5 ○ A damper configured to move among a fully open position in which the damper allows a heated exhaust stream to flow through an exhaust port, a closed position in which the damper prevents the heated exhaust stream from flowing through the exhaust port, and a plurality of intermediate open positions between the fully open and closed positions.
- 10 ○ A damper controller configured to move a damper between fully open and closed positions based, at least in part, on a detected temperature in a hydrogen-producing region.
- A damper controller configured to move a damper between fully open and closed positions based, at least in part, on a detected temperature in at least one of a  
15 hydrogen-producing region and a purification region.
- A damper controller configured to move a damper toward a closed position when a detected temperature is above a predetermined maximum temperature.
- A damper controller configured to move a damper toward an open position when a detected temperature is below a predetermined minimum temperature.
- 20 ○ A buffer tank configured to contain a product hydrogen stream.
- A product conduit fluidly connecting a fuel processing assembly and a buffer tank.
- A tank sensor assembly configured to detect pressure in a buffer tank.

- A product valve assembly configured to manage flow in a product conduit.
- At least one valve that is configured to operate between a flow position in which a product hydrogen stream from a fuel processing assembly flows through a product conduit and into a buffer tank, and a vent position in which the product  
5 hydrogen stream from the fuel processing assembly is vented prior to the buffer tank.
- A three-way solenoid valve.
- A first valve configured to control flow of a product hydrogen stream between a fuel processing assembly and a buffer tank.
- 10 ○ A first valve configured to move between a first open position in which a product hydrogen stream flows between a fuel processing assembly and a buffer tank, and a first closed position in which the product hydrogen stream does not flow between the fuel processing assembly and the buffer tank.
- A second valve configured to vent a product hydrogen stream from a fuel  
15 processing assembly.
- A second valve configured to move between a second open position in which a product hydrogen stream is vented, and a second closed position in which the product hydrogen stream is not vented.
- A control assembly configured to operate a fuel processing assembly between  
20 run and standby modes based, at least in part, on detected pressure.
- A control assembly configured to operate a fuel processing assembly in a standby mode when detected pressure in a buffer tank is above a predetermined maximum pressure.

- A control assembly configured to operate a fuel processing assembly in a run mode when detected pressure in a buffer tank is below a predetermined minimum pressure.
- 5 ○ A control assembly configured to direct a product valve assembly to vent a product hydrogen stream from a fuel processing assembly when the fuel processing assembly is in the standby mode.
- A control assembly configured to move at least one valve to a flow position when a fuel processing assembly is in a run mode.
- 10 ○ A control assembly configured to move at least one valve to a vent position when a fuel processing assembly is in a standby mode.
- A control assembly configured to move a first valve to a first open position and a second valve to a second closed position when a fuel processing assembly is in a run mode.
- 15 ○ A control assembly configured to move a first valve to a first closed position and a second valve to a second open position when a fuel processing assembly is in a standby mode.

## INDUSTRIAL APPLICABILITY

The present disclosure, including hydrogen generation assemblies, hydrogen purification devices, and components of those assemblies and devices, is applicable to the fuel-processing and other industries in which hydrogen gas is purified, produced,  
5 and/or utilized.

The disclosure set forth above encompasses multiple distinct inventions with independent utility. While each of these inventions has been disclosed in its preferred form, the specific embodiments thereof as disclosed and illustrated herein are not to be considered in a limiting sense as numerous variations are possible. The subject matter  
10 of the inventions includes all novel and non-obvious combinations and subcombinations of the various elements, features, functions and/or properties disclosed herein. Similarly, where any claim recites “a” or “a first” element or the equivalent thereof, such claim should be understood to include incorporation of one or more such elements, neither requiring nor excluding two or more such elements.

15 Inventions embodied in various combinations and subcombinations of features, functions, elements, and/or properties may be claimed through presentation of new claims in a related application. Such new claims, whether they are directed to a different invention or directed to the same invention, whether different, broader, narrower or equal in scope to the original claims, are also regarded as included within the subject  
20 matter of the inventions of the present disclosure.

## WHAT IS CLAIMED IS:

1. A hydrogen generation assembly, comprising:
  - a fuel processing assembly configured to receive a feed stream and produce a product hydrogen stream from the feed stream;
  - 5 a feed assembly configured to deliver the feed stream to the fuel processing assembly, the feed assembly including:
    - a feed tank configured to contain feedstock for the feed stream,
    - a feed conduit fluidly connecting the feed tank and the fuel processing assembly, and
    - 10 a pump configured to deliver the feed stream at a plurality of flowrates to the fuel processing assembly via the feed conduit; and
    - a control system, including:
      - a feed sensor assembly configured to detect pressure in the feed conduit downstream from the pump, and
      - 15 a pump controller configured to select a flowrate from the plurality of flowrates based on the detected pressure in the feed conduit, and to operate the pump at the selected flowrate.
2. The assembly of claim 1, wherein the pump controller is further configured  
20 to select the flowrate based solely on the detected pressure in the feed conduit.
3. The assembly of claim 1, wherein the feed sensor assembly is further configured to generate a signal based on the detected pressure in the feed conduit, the

pump controller being further configured to condition the signal received from the sensor assembly and to select the flowrate based on the conditioned signal.

4. The assembly of claim 3, wherein the pump controller is further configured  
5 to invert the signal received from the feed sensor assembly and to select the flowrate based on the inverted signal.

5. The assembly of claim 1, further comprising a purge assembly, including:  
a pressurized gas assembly fluidly connected to the feed conduit and configured  
10 to receive at least one container of pressurized gas that is configured to purge the fuel processing assembly; and

a purge valve assembly configured to allow the at least one pressurized gas to flow through the feed conduit from the pressurized gas assembly to the fuel processing assembly when power to the fuel processing assembly is interrupted.

15

6. The assembly of claim 1, further comprising an enclosure having an exhaust port, the fuel processing assembly including a hydrogen-producing region contained within the enclosure and configured to provide, via a steam reforming reaction, the product hydrogen stream from the feed stream, wherein the control system  
20 further includes a reformer sensor assembly configured to detect temperature in the hydrogen-producing region.

7. The assembly of claim 6, further comprising:

a heating assembly configured to receive at least one air stream and at least one fuel stream and to combust the at least one fuel stream within a combustion region contained within the enclosure producing a heated exhaust stream for heating at least the hydrogen-producing region to at least a minimum hydrogen-producing temperature; and

a damper moveably connected to the exhaust port and configured to move among a plurality of positions including a fully open position in which the damper allows the heated exhaust stream to flow through the exhaust port, a closed position in which the damper prevents the heated exhaust stream from flowing through the exhaust port, and a plurality of intermediate open positions between the fully open and closed positions, and wherein the control system further includes a damper controller configured to move the damper between the fully open and closed positions based, at least in part, on the detected temperature in the hydrogen-producing region.

15

8. The assembly of claim 1, wherein the fuel processing assembly is further configured to be operable among a plurality of modes, including a run mode in which the fuel processing assembly produces the product hydrogen stream from the feed stream, and a standby mode in which the fuel processing assembly does not produce the product hydrogen stream from the feed stream.

20

9. The assembly of claim 8, further comprising a buffer tank configured to contain the product hydrogen stream, and a product conduit fluidly connecting the fuel processing assembly and the buffer tank, wherein the control system further includes:

a product sensor assembly configured to detect pressure in the buffer tank, and

5 a control assembly configured to operate the fuel processing assembly between the run and standby modes based, at least in part, on the detected pressure in the buffer tank.

10. A hydrogen generation assembly, comprising:

10 a fuel processing assembly configured to receive a feed stream and produce a product hydrogen stream from the feed stream;

a pressurized gas assembly configured to receive at least one container of pressurized gas that is configured to purge the fuel processing assembly;

15 a purge conduit configured to fluidly connect the pressurized gas assembly and the fuel processing assembly; and

a purge valve assembly configured to allow the at least one pressurized gas to flow through the purge conduit from the pressurized gas assembly to the fuel processing assembly when power to the fuel processing assembly is interrupted.

20 11. The assembly of claim 10, wherein the purge valve assembly includes a purge valve that moves between a closed position in which the at least one pressurized gas does not flow through the purge conduit from the pressurized gas assembly, and an

open position in which the at least one pressurized gas is allowed to flow through the purge conduit from the pressurized gas assembly.

12. The assembly of claim 11, wherein the purge valve is in the closed  
5 position when there is power to the fuel processing assembly, and wherein the purge valve automatically moves to the open position when power to the fuel processing assembly is interrupted.

13. The assembly of claim 11, wherein the purge valve assembly further  
10 includes a purge solenoid configured to move the purge valve between the open and closed positions, the fuel processing assembly including a control system configured to send a control signal to the purge solenoid, and wherein the purge solenoid is configured to move the purge valve to the closed position when the purge solenoid receives the control signal, and to automatically move the purge valve to the open  
15 position when the purge solenoid does not receive the control signal.

14. The assembly of claim 10, wherein at least a portion of the fuel processing assembly and at least a portion of the purge assembly are contained within an enclosure.

20

15. A steam reforming hydrogen generation assembly configured to receive at least one feed stream and generate a reformat stream containing hydrogen gas as a majority component and other gases, comprising:

an enclosure having an exhaust port;

a hydrogen-producing region contained within the enclosure and configured to produce, via a steam reforming reaction, the reformat stream from the at least one feed stream;

5 a reformer sensor assembly configured to detect temperature in the hydrogen-producing region;

a heating assembly configured to receive at least one air stream and at least one fuel stream and to combust the at least one fuel stream within a combustion region contained within the enclosure producing a heated exhaust stream for heating at least  
10 the hydrogen-producing region to at least a minimum hydrogen-producing temperature; and

a damper moveably connected to the exhaust port and configured to move among a plurality of positions including a fully open position in which the damper allows the heated exhaust stream to flow through the exhaust port, a closed position in which  
15 the damper prevents the heated exhaust stream from flowing through the exhaust port, and a plurality of intermediate open positions between the fully open and closed positions, and

a damper controller configured to move the damper between the fully open and closed positions based, at least in part, on the detected temperature in the hydrogen-  
20 producing region.

16. The assembly of claim 15, further comprising a purification region contained within the enclosure and including a hydrogen-selective membrane, the

purification region being configured to produce a permeate stream comprised of the portion of the reformat stream that passes through the hydrogen-selective membrane, and a byproduct stream comprised of the portion of the reformat stream that does not pass through the membrane, wherein the reformer sensor assembly is further  
5 configured to detect temperature in the purification region and the damper controller is configured to move the damper between the fully open and closed positions based, at least in part, on the detected temperature in at least one of the hydrogen-producing region and the purification region.

10 17. The assembly of claim 15, wherein the damper controller is configured to move the damper toward the closed position when the detected temperature is above a predetermined maximum temperature.

15 18. The assembly of claim 15, wherein the damper controller is configured to move the damper toward the fully open position when the detected temperature is below a predetermined minimum temperature.

19. The assembly of claim 15, further comprising:  
a purge gas assembly configured to receive at least one container of pressurized  
20 gas that is configured to purge the hydrogen-producing region;  
a purge conduit configured to fluidly connect the pressurized gas assembly and the hydrogen-producing region; and

a purge valve assembly configured to allow the at least one pressurized gas to flow through the purge conduit from the pressurized gas assembly to the hydrogen-producing region when power to the hydrogen-producing region is interrupted.

5           20. The assembly of claim 19, further comprising a purification region contained within the enclosure and fluidly connected to the hydrogen-producing region, the purification region including a hydrogen-selective membrane, the at least one container of pressurized gas being configured to purge the hydrogen-selective membrane, and the purge valve assembly being configured to allow the at least one  
10 pressurized gas to flow through the purge conduit from the pressurized gas assembly to the hydrogen-selective membrane when power to the hydrogen-producing region is interrupted.

15           21. The assembly of claim 15, wherein the hydrogen-producing region is configured to be operable between a plurality of modes, including a run mode in which the hydrogen-producing region produces the reformat stream from the at least one feed stream, and a standby mode in which the hydrogen-producing region does not produce the reformat stream from the at least one feed stream, the assembly further comprising:

20           a buffer tank configured to contain the reformat stream;

          a product conduit fluidly connecting the hydrogen-producing region and the buffer tank;

a buffer tank sensor assembly configured to detect pressure in the buffer tank;  
and

a reformer controller configured to operate the hydrogen-producing region  
between the run and standby modes based, at least in part, on the detected pressure in  
5 the buffer tank.

22. A hydrogen generation assembly, comprising:

a fuel processing assembly configured to receive a feed stream and to be  
operable among a plurality of modes, including a run mode in which the fuel processing  
10 assembly produces a product hydrogen stream from the feed stream, and a standby  
mode in which the fuel processing assembly does not produce the product hydrogen  
stream from the feed stream;

a buffer tank configured to contain the product hydrogen stream;

a product conduit fluidly connecting the fuel processing assembly and the buffer  
15 tank;

a tank sensor assembly configured to detect pressure in the buffer tank; and

a control assembly configured to operate the fuel processing assembly between  
the run and standby modes based, at least in part, on the detected pressure in the  
buffer tank.

20

23. The assembly of claim 22, wherein the control assembly is configured to  
operate the fuel processing assembly in the standby mode when the detected pressure  
in the buffer tank is above a predetermined maximum pressure.

24. The assembly of claim 22, wherein the control assembly is configured to operate the fuel processing assembly in the run mode when the detected pressure in the buffer tank is below a predetermined minimum pressure.

5

25. The assembly of claim 22, further comprising a product valve assembly configured to manage flow in the product conduit, wherein the control assembly is configured to direct the product valve assembly to vent the product hydrogen stream from the fuel processing assembly when the fuel processing assembly is in the standby  
10 mode.

26. The assembly of claim 25, wherein the product valve assembly includes at least one valve that is configured to operate between a flow position in which the product hydrogen stream from the fuel processing assembly flows through the product  
15 conduit and into the buffer tank, and a vent position in which the product hydrogen stream from the fuel processing assembly is vented prior to the buffer tank.

27. The assembly of claim 26, wherein the control assembly is further configured to move the at least one valve to the flow position when the fuel processing  
20 assembly is in the run mode.

28. The assembly of claim 26, wherein the control assembly is further configured to move the at least one valve to the vent position when the fuel processing assembly is in the standby mode.

5 29. The assembly of claim 26, wherein the at least one valve is a three-way valve.

30. The assembly of claim 26, wherein the at least one valve includes a first valve configured to control flow of the product hydrogen stream between the fuel  
10 processing assembly and the buffer tank, and a second valve configured to vent the product hydrogen stream from the fuel processing assembly.

31. The assembly of claim 30, wherein the first valve is configured to move between a first open position in which the product hydrogen stream flows between the  
15 fuel processing assembly and the buffer tank, and a first closed position in which the product hydrogen stream does not flow between the fuel processing assembly and the buffer tank, wherein the second valve is configured to move between a second open position in which the product hydrogen stream is vented, and a second closed position in which the product hydrogen stream is not vented.

20

32. The assembly of claim 31, wherein the control assembly is further configured to move the first valve to the first open position and the second valve in the second closed position when the fuel processing assembly is in the run mode.

33. The assembly of claim 32, wherein the control assembly is further configured to move the first valve to the first closed position and the second valve in the second open position when the fuel processing assembly is in the standby mode.

5

34. The assembly of claim 22, further comprising:

a purge gas assembly configured to receive at least one container of pressurized gas that is configured to purge the fuel processing assembly;

10 a purge conduit configured to fluidly connect the pressurized gas assembly to the fuel processing assembly; and

a purge valve assembly configured to allow the at least one pressurized gas to flow through the purge conduit from the pressurized gas assembly to the fuel processing assembly when the fuel processing assembly is in the standby mode.

15 35. The assembly of claim 22, further comprising:

a purge gas assembly configured to receive at least one container of pressurized gas that is configured to purge the fuel processing assembly;

a purge conduit configured to fluidly connect the pressurized gas assembly to the fuel processing assembly; and

20 a purge valve assembly configured to allow the at least one pressurized gas to flow through the purge conduit from the pressurized gas assembly to the fuel processing assembly when power to the fuel processing assembly is interrupted.

| X         | US 2006/0090397 A1 (EDLUND et al.) 04 May 2006 (04.05.2006), para [0040], [0041], [0044], [0046], [0053], [0056], [0082], [0083], [0087], [0088], [0090], [0098], [0104], [0113], [0116], [0123], [0165], [0175], [0179], [0185], [0188], [0190], [0193], [0201], [0221], [0222]; abstract; figures 2, 6, 15, and 29; claim 1 | 1, 2, 6, 8               |
| Y         |   | 3-5, 7, 9-35             |
| Y         | WO 2003/041188 A2 (RUSTA-SALLEHY et al.) 15 May 2003 (15.05.2003), para [0012], [0033], [0040]; figure 1; claims 17 and 23  | 3, 4, 9, 21-35           |
| Y         | US 2003/0087138 A1 (MARGIOTT et al.) 08 May 2003 (08.05.2003), para [0004], [0006], [0012], [0027], [0034], [0036]; claim 1; abstract figure 1 and 2  | 5, 10-14, 19, 20, 34, 35 |
| Y         | WO 2012/091121 A1 (MIZUNO et al.) 05 July 2012 (05.07.2012) -- [see machine translation] para [0037], [0045], [0048], [0049]  | 7, 15-21                 |
| Y         | US 2004/0066043 A1 (MAIWALD et al.) 08 April 2004 (08.04.2004), para [0042], [0045]   | 4                        |
| A         | US 2006/0144700 A1 (CARSON et al.) 06 July 2006 (06.07.2006), entire document   | 1                        |
| A         | US 2008/0075987 A1 (KINDLER et al.) 27 March 2008 (27.03.2008), entire document   | 1                        |
| A         | US 2008/0222954 A1 (ADAMS et al.) 18 Sep 2008 (18.09.2008), entire document   | 1                        |

☐ Further documents are listed in the continuation of Box C.

\* Special categories of cited documents:

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier application or patent but published on or after the international filing date

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

"&amp;" document member of the same patent family

Date of the actual completion of the international search

05 January 2014 (05.01.2014)

Date of mailing of the international search report

24 JAN 2014
