TITLE OF THE INVENTION
COMBINATION METHOD FOR ACNE TREATMENT

BACKGROUND OF THE INVENTION

The present invention is directed to a combination method for treating acne using selective 5α-reductase 1 inhibitors, 5α-reductase 2 inhibitors, combinations thereof, or dual inhibitors, including but not limited to: 7β-substituted-4-aza-5α-cholestan-3-ones and related 4-aza-5α-androstan-3-one compounds, together with a retinoid agent, e.g., tretinoin or isotretinoin, and at least one agent selected from an antibacterial, a keratolytic, an anti-inflammatory agent, or mixture thereof.

DESCRIPTION OF THE PRIOR ART

Acne vulgaris is the most common skin condition evaluated and managed by physicians in the United States. It is estimated that more than 17 million people have some degree of acne. While it is most prevalent in adolescents, nearly 85% of 12-24 year olds, 8% of 25-34 year olds, and 3% of 35-55 year olds have acne. In 1990, nearly 4.5 million patient visits to dermatologists were for acne-related problems: an additional 500,000 visits were to primary care providers.

Acne is basically an androgen dependent disorder. Its peak incidence is at age 18, and it is more prevalent in men than in women. In some cases, it can be severe enough to cause significant scarring that does not resolve. In many patients, its presence is psychologically distressing. While it is not a life-threatening condition, it can have significant psychosocial effects on those who suffer with it. Acne has also been shown to be associated with impaired academic and social functioning, as well as to affect employment status. Thus, the accurate assessment and appropriate management of acne can have important consequences on the overall well-being and quality of life of the patient with acne.

Sebum is one of the major factors, along with abnormal keratinization of the follicular epithelium, inflammation and colonization
by the bacterium \textit{P. acnes}, that causes acne. Since all of these factors are inter-related, affecting just one, e.g., sebum production, can have a profound influence on acne.

The hormonal milieu plays an important role in modulating sebum production in males and females. In children, onset of acne and sebum secretion occur coincident with the increasing androgens that accompany adrenarche and pubarche. Administration of androgens worsens acne and increases sebum production, while administration of estrogens decreases sebum production and is associated with an improvement in acne. Antiandrogens, such as ciproterone and spironolactone, are sometimes used for the treatment of acne in women. Although these clinical observations provided convincing evidence that androgens modulate sebum production, it had been uncertain which of the androgens plays the most important role.

It is now known in the art that the principal mediator of androgenic activity in some target organs is \(5\alpha\)-dihydrotestosterone (DHT), and that it is formed locally in the target organ by the action of testosterone-\(5\alpha\)-reductase. It is also known that inhibitors of testosterone-\(5\alpha\)-reductase will serve to prevent or lessen symptoms of hyperandrogenic stimulation.

However, despite the suggestion in the prior art that hyperandrogenetic diseases are the result of a single 5α-reductase, there are reports regarding the presence of other 5α-reductase isozymes in both rats and humans. For example, in human prostate, Bruchovsky, et al. (See J. Clin. Endocrinol. Metab. 67, 806-816, 1988) and Hudson (see J. Steroid Biochem. 26, p 349-353, 1987) found different 5α-reductase activities in the stromal and epithelial fractions. Additionally, Moore and Wilson described two distinct human reductases with peaks of activities at either pH 5.5 or pH 7-9. (See J. Biol. Chem. 251, 19, p. 5895-5900, 1976).

Recently, Andersson and Russell isolated a cDNA which encodes a rat liver 5α-reductase (see J. Biol. Chem. 264 pp. 16249-55 (1989). They found a single mRNA which encodes both the liver and prostatic reductases of rats. The sequence of this rat gene was later used to select a human prostatic cDNA encoding a 5α-reductase termed "5α-reductase 1". (See Proc. Nat'l. Acad. Sci. 87, p. 3640-3644, 1990).

More recently, a second, human prostatic reductase (5α-reductase 2) has been cloned with properties identified with the more abundant form found in crude human prostatic extracts. (See Nature, 354, p. 159-161, 1991).

Thus, the art supports the existence of at least two genes for 5α-reductase and two distinct isozymes of 5α-reductase in humans. The isozyme that principally interacts in certain skin tissues, e.g., skin or scalp, is conventionally designated as 5α-reductase 1 (or 5α-reductase type 1), while the isozyme that principally interacts within the prostatic tissues is designated as 5α-reductase 2 (or 5α-reductase type 2). See, e.g., G. Harris, et al., Proc. Natl. Acad. Sci. USA, Vol. 89, pp. 10787-10791 (Nov. 1992).

Local dihydrotestosterone (DHT) formation via 5α reductase (5alphaR) plays a major role in sebum production and the pathophysiology of acne since it is known that the sebaceous gland is rich
in 5 alpha reductase and that acne prone skin contains excessive 5 alphaR activity. On this basis, local DHT formation is responsible for increased sebum production in sebaceous follicles of acne prone tissue and 5 alpha R\textsuperscript{1} or R\textsuperscript{2} inhibition, or combination thereof, can be useful in the treatment of acne.

As described above, acne is a disease with multifactorial pathogenesis including the factors of: (a) increased sebum production, (b) follicular keratinization, (c) Propionibacterium acnes proliferation and (d) inflammation. On this basis, we believe that its effective management can best be brought about through combination therapy that concurrently addresses more than one of these pathogenic factors in a therapeutic protocol. In the treatment of acne vulgaris, it would be desirable to employ a 5\alpha-reductase 1 or 2 inhibitor, combination thereof, or a dual inhibitor, which decreases sebum production, in combination with another agent to amplify the therapy against the other above-described pathogenic factors in the treatment.

Therefore it is an object of this invention to provide a combination method of agents that has sufficient activity in the inhibition of 5\alpha-reductase isozyme 1, 5\alpha-reductase isozyme 2, combination thereof, or the use of a dual inhibitor, in combination with another agent that will enhance the effectiveness of the 5\alpha-reductase 1 or 2 inhibitor, or combination thereof, in the treatment of acne vulgaris.

SUMMARY OF THE INVENTION

By this invention there is provided a combination method involving the use of a 5\alpha-reductase 1 and/or 2 inhibitor, in combination with a retinoid agent, including but not limited to, e.g., tretinoin (all-trans-retinoic acid, RETIN A) and isotretinoin (13-cis-retinoic acid, ACCUTANE), and at least one agent selected from: an antibacterial, an anti-inflammatory, and a keratolytic, or combination thereof, in the treatment of acne vulgaris by topical and/or systemic administration.

The 5 alpha reductase 1 or 2 inhibitor inhibits the production of sebum while concurrently: the retinoid normalizes desquamation of the
follicular epithelium, promotes drainage of preexisting comedones, inhibits the formation of new ones and can decrease the production of sebum, especially isotretinoin; the antibacterial improves both inflammatory and non-inflammatory lesions by reducing the population of Propionibacterium acnes and other Gram-negative and Gram-positive bacteria on the skin surface and within the follicles; the keratolytic, decreases follicular keratinization; and the anti-inflammatory decrease inflammation and can lead to a mild drying and peeling of the skin. This combination of agents leads to a more effective method of treatment than use of either agent alone.

The invention is still further concerned with pharmaceutical formulations comprising one or more inhibitors of 5α-reductase 1 or 2, or combination thereof, or a dual inhibitor, in combination with a retinoid agent, e.g., tretinoin or isotretinoin, and at least one agent selected from an antibacterial, a keratolytic, and an anti-inflammatory, or combination thereof.

In one embodiment of this invention, is a method of treating acne employing 5α reductase 1 inhibitors, i.e., 7β-substituted-4-aza-5α-cholestan-3-ones and 5α-androstan-3-one compounds, which are selected from the group consisting of the generic Formulae (I.):

The following discussion applies to terms used in both
Formulae I and II.

As used herein "alkyl" is intended to include both branched-
and straight-chain saturated aliphatic hydrocarbon groups having the
specified number of carbon atoms, e.g., methyl (Me), ethyl (Et), propyl,
butyl, pentyl, hexyl, heptyl, octyl, nonyl, decyl, iso-propyl (i-Pr), iso-

include hydrocarbon groups of either a straight or branched configuration
with one or more carbon-carbon double bonds which may occur in any
stable point along the chain, such as ethenyl, propeny1 or allyl, buteny1,

Where a basic group is present, i.e., amino or a basic heteroaryl radical such as, e.g., 4-pyridyl, an acidic salt, i.e., hydrochloride, hydrobromide, acetate, pamoate, and the like, can be used as the dosage form.
Also, in the case of the -COOH group being present, pharmaceutically acceptable esters can be employed, e.g., acetate, maleate, pivaloyloxymethyl, and the like, and those esters known in the art for modifying solubility or hydrolysis characteristics for use as sustained release or prodrug formulations.

In addition, some of the compounds of the instant invention may form solvates with water or common organic solvents. Such solvates are encompassed within the scope of this invention.

The compounds of Formula I and II of the present invention have asymmetric centers and may occur as racemates, racemic mixtures and as individual enantiomers or diastereomers, with all isomeric forms being included in the present invention as well as mixtures thereof. Furthermore, some of the crystalline forms for compounds of the present invention may exist as polymorphs and as such are intended to be included in the present invention.

The term "therapeutically effective amount" shall mean that amount of a drug or pharmaceutical agent that will elicit the biological or medical response of a tissue, system, animal or human that is being sought by a researcher, veterinarian, medical doctor or other clinician.

The compounds of the instant invention comprising Z as a 7β alkyl group, e.g., methyl, ethyl, isopropyl, allyl, can be prepared by the procedure outlined in The General Flowsheet.

As seen in the Flowsheet, the starting 3-acetoxy-cholest-5-ene I (see Example 1 for synthesis) is oxidized to the corresponding 5-en-7-one II by treatment with hydrogen t-butyl peroxide and chromium hexacarboxyl in e.g., acetonitrile, at reflux. The C1-C4 alkyl group, designated Alk, e.g., methyl, can be introduced at this point by a Grignard reaction using e.g., alkyl magnesium chloride in e.g., anhydrous tetrahydrofuran (THF) at 0-23°C to produce the 7-alkyl-7-hydroxy adduct III. This is then oxidized with e.g., aluminum isopropoxide and cyclohexanone (Oppenauer oxidation conditions) in refluxing toluene solvent to produce the 7-alkyl-4,6-dien-3-one IV. This in turn is reduced via a e.g., metal-ammonia reduction, using lithium, liquid ammonia, THF and toluene at -78°C, quenching the reaction with dibromothane and ammonium chloride, to selectively yield the 7-beta-alkyl-5-en-3-one V. In the next step the delta-5 double bond is isomerized to the 4-ene by use of DBU (1,8-diazabicyclo-[5.4.0]undec-7-ene) in e.g., refluxing THF to produce the 7-beta-alkyl 4-en-3-one, VI. The A Ring is next cleaved by treatment with e.g., potassium permanganate, sodium periodate in t-butyl alcohol at 80°C to produce the corresponding seco-acid VII. Treatment of the seco-acid with an appropriate amine e.g., methylamine hydrochloride and sodium acetate in ethylene glycol at 180°C, yields e.g., the 4-methyl-4-aza-cholest-5-en-3-one VIII. This in turn is selectively reduced with e.g., PtO₂ catalyst in a hydrogen atmosphere, to remove the 5-position double bond to produce the 5α-hydrogen compound IX. The seco-acid VII can be similarly treated with ammonium acetate in acetic acid (HOAc) to produce the corresponding N-H compound, X, which can then be analogously treated with PtO₂ in a catalytic hydrogenation to produce the corresponding 5α-4N-H compound XI. Similarly, use of hydroxylamine or hydrazine for ring A closure of the seco acid will afford the corresponding delta-5-4N-X compounds where -X can be -OH or -NH₂, respectively. Reaction of the anion of saturated 4N-compound
(generated from the NH precursor by NaH treatment) with methylsulfenyl chloride can provide the corresponding 4N-X compound where -X is -SCH₃. Thus, R can also be -OH, -NH₂ or SCH₃ in the Formula.

7-Beta-Ethyl-Cholestan Analogues

The 7-ethyl substituent is introduced into the cholestan series as illustrated in Flowsheets C and D by the same analogous procedure as described in the General Flowsheets.

The starting cholesteryl acetate CA is available commercially (Aldrich). This is treated using the analogous chromium hexacarbonyl/hydrogen t-butylperoxide/acetonitrile oxidation procedure (described in JCS Perkin Trans. 1985, p. 267 by A. J. Pearson) to yield the 3-acetoxy-cholest-5-en-7-one 1. This can be reacted with an alkyl Grignard reagent, e.g., ethyl magnesium chloride to form the adduct 2. This is oxidized under Oppenauer conditions to yield the dieneone 3, which then can undergo metal-ammonia reduction to yield the 7β-ethyl-5-en-3-one, 4. This is isomerized using DBU to the 4-en-3-one, 5, which is oxidized to open Ring A to yield the seco-acid 6. This can be treated with amines, e.g. methylamine, to yield the A-ring closed 4-methyl-4-aza compound 7. This in turn can be catalytically hydrogenated to yield the 7-ethyl-5-alpha-4-methyl-4-aza-cholestan-3-one, 8.

Similarly, by treatment of the seco-acid 6 with ammonium acetate/acetic acid, the corresponding 4-NH analog 9, is produced which can be catalytically hydrogenated to yield the 7-beta-ethyl-5alpha-4-aza-cholestan-3-one, 10.

Following the same procedure but using phenylmagnesium chloride as the Grignard reagent, the corresponding compounds 50 and 51 are produced ("Ph" represents phenyl).

7-Carboxymethyl-Cholestane Series

The 7-carboxy substituent is formed through the corresponding 7-allyl group. As seen in Flowsheet C, 7-oxo-cholesteryl acetate 1 is reacted with allyl Grignard reagent to form the adduct 11 which is oxidized to the dienone 12 by Oppenauer conditions. Metal-ammonia reduction affords the 5-ene analog 13, followed by DBU-catalyzed double bond isomerization to 14. This in turn can be oxidized in a key step to form the 7-carboxymethyl seco-acid 15. Treatment with amines, e.g., ammonia, forms the 4-aza derivative, 16 which is then reduced to the cholestane 17. Use of methylamine in place of ammonia can yield the corresponding 4-methyl analogs of 16 and 17.

The methyl Grignard reagent is used to form the adduct 24, followed by Oppenauer oxidation to form 25, metal-ammonia reduction to form 26, double bond isomerization to form 27, seco-acid oxidation to form 28, and treatment by an ammonium salt to form 29, and reduction to form 30. 7-Beta Acetoxy Cholestane Series

The 7-beta acetoxy series is prepared by the oxidation of starting \( \text{33} \) to the 5-en-7-one \( \text{34} \) by the chromium hexacarbonyl procedure described for 1, or by pyridine-dichromate/t-butyl hydroperoxide oxidation as described in the Examples. Subsequent noble metal, e.g., platinum, ruthenium, catalyzed reduction of \( \text{34} \) yields two products, the reduced 7-oxo compound \( \text{35} \), and 7-beta hydroxy compound \( \text{36} \). Acylation of \( \text{36} \) with acetic anhydride (Ac₂O) yields the 7-beta acetoxy compound \( \text{37} \). DMAP is dimethylaminopyridine; Py is pyridine; Ac is acetyl.

**FLOWSHEET J**

![Diagram](attached-diagram)
The 7-beta ethers in the cholestane series are prepared from the 7-beta-ol (7-beta hydroxy derivative). As illustrated in Flowsheet J, the 4-N-methyl-7-beta ol \( 36 \) can be reacted with e.g., methyl iodide and sodium hydride in e.g., dimethylformamide, to produce the corresponding methyl ether \( 37 \). The other C1-C4 ethers can be prepared in the same manner.

The C3-C6 cycloalkyl ethers can be prepared according to the analogous procedure of *Steroids*, 1972, vol. 19, pp. 639-647 by R. Gardi, *et al.* For example, \( 36 \) can be reacted with 1,1-dimethoxy-cyclohexane to produce the enol ether \( 38 \), which can be reduced to the corresponding saturated compound by the use of palladium catalyzed hydrogenation.

FLOWSHEET L

FLOWSHEET M
The 7-haloalkyl series is made by the procedure illustrated in Flowsheet K.

Starting with the 7-beta-carboxy, 45, this can be treated under Hunsdiecker reaction conditions, i.e., bromination of a mercury metal salt, to yield the 7-bromo derivative 40. The chloro and iodo derivatives can be made in substantially the same fashion.

The haloethyl compounds can be made by starting with the 7-carboxymethyl analog 17 which can be reacted with a reducing agent, e.g., borane, to produce the primary alcohol 41. This in turn can be reacted with triphenylphosphine and carbon tetrabromide to produce the bromoethyl derivative 42.

The halomethyl compounds can be produced starting with the carboxymethyl derivative 17. This is treated with lead tetraacetate under oxidative decarboxylation/halogenation conditions, with a chloride, bromide or iodide salt to yield, e.g., the 7-chloromethyl analog 43. The carboxymethyl compound 17 can be treated with a fluorinating agent (XeF2) to yield the 7-fluoromethyl analog 44.

The 7-trifluoromethyl derivative can be made from the 7-carboxy derivative 45, by conventional Dast halogenation conditions using SF4 to yield the 7-trifluoromethyl analog 46.
Flowsheet N illustrates the 7-methylene series. As seen, the Wittig reaction, using e.g., Ph₃PCH(CH₂CH₃), carried out on the 7-oxo compound 35, leads to the 7-(ethyl)methylene compound 47.

Subsequent treatment of 47 with the cyclopropyl forming reagents, CH₂I₂ and zinc, produces the ethyl cyclopropyl spiro compound 48, which is a mixture of stereoisomers.
Flowsheet O illustrates the synthesis of the 1-ene 7-substituted analogs. For example compound 30 is stirred with DDQ, BSTFA (bis-trimethylsilyltrifluoroacetamide) and trifluoromethyl sulfonic acid in toluene at room temperature for 24 hours, methyl acetoacetate is added and the mixture refluxed for 24 hours and purified by preparative thin layer chromatography on silica gel using 3:1 chloroform/acetone to yield 49.

**Formula II**

The compounds of Formula II useful in the present invention can be prepared readily according to the following reaction Schemes and Examples or modifications thereof using readily available starting
materials, reagents and conventional synthesis procedures. In these reactions, it is also possible to make use of variants which are themselves known to those of ordinary skill in this art, but are not mentioned in greater detail. Specific definitions of variables in the Schemes are illustrative only, and are not intended to limit the procedures described. Some abbreviations used herein are as follows: Ph is phenyl; Ac is an acyl group; t-Bu is tert-buty1; Et is ethyl; Me is methyl; i-Am is iso-amyl; EtOAc is ethyl acetate.

The inhibitors described in Scheme 1 can be prepared as follows. 4-Aza-4-methyl-5α-androstan-3,17-dione (A) is first converted into the isomeric 3,16-dione (52) by the following sequence of reactions: (1) treatment of A with isoamyl nitrite in t-butanol in the presence of potassium t-butoxide to generate the intermediate 16-oximino-17-ketone; (2) reduction of the 17-keto group with hydrazine hydrate and potassium hydroxide in ethylene glycol at elevated temperatures to give 16-oxime (B); and (3) cleavage of the 16-oximino group in B either by hydrolysis with aqueous acetic acid at elevated temperatures or with sodium bisulfite followed by treatment with aqueous hydrochloric acid to afford (52). Reduction of the 16-ketone (52) to the 16β-alcohol (53) is carried out with a suitable hydride-based reducing agent, such as sodium borohydride in methanol or lithium tri-sec-buty1borohydride in tetrahydrofuran (THF). Alcohol (53) is converted into its alkyl ether derivatives (54) and (55), by first generating the alkoxide anion with potassium hydride in N,N-dimethylformamide (DMF) or potassium hydroxide in dimethyl sulfoxide (DMSO) followed by addition of the appropriate alkyl bromide or iodide. The 16β-(n-propyloxy) derivative (56) is obtained from the precursor 16β-(allyloxy) derivative (55) by catalytic hydrogenation.

The inhibitors described in Scheme 2 can be prepared as follows. 16-Oxime (B) is converted into the 16β-amine (C) by catalytic hydrogenation in the presence of a heterogeneous catalyst such as platinum oxide in aqueous acetic acid. Acylation of (C) is effected with the appropriate acid anhydride or acid chloride in the presence of an acid acceptor such as pyridine, triethylamine, and 4-dimethylaminopyridine.
In this fashion are obtained Examples 6 and 7. Carbamates, such as (59) depicted in Scheme 3, are made by treatment of alcohol (53) with the appropriate isocyanate in the presence of an organic base, such as triethylamine, pyridine, and 4-dimethylaminopyridine.

The inhibitors described in Scheme 4 can be prepared as follows. The 16β-alcohol (53) is converted into the 16α-alcohol (60) by treatment with 4-nitro-benzoic acid in the presence of diethyl azadicarboxylate (DEAD) and triphenylphosphine to generate the intermediate 16α-(p-nitrobenzoate) ester (D) followed by hydrolysis in aqueous base in an appropriate alcohol solvent. Alkylation of (60) is carried out in an analogous fashion as described above with alcohol (53) to yield the desired 16α-alkyl ethers, such as the 16α-methoxy derivative (Example 10) shown in Scheme 4.

The 7β-methyl inhibitors described in Scheme 5 are prepared in a similar manner as that described above for the examples in Scheme 1, but using instead as starting material, 4-aza-4,7β-dimethyl-5α-androstan-3,17-dione (E).

The 7β-methyl inhibitors described in Scheme 6 are prepared as follows. Compound (71) is prepared by treatment of alcohol (63) with t-butyl trichloroacetimidate in the presence of an organic sulfonic acid, such as trifluoromethanesulfonic acid. The 16β-aryloxy derivatives, such as Compounds 72-75, are obtained by first generating the alkoxide anion from alcohol (63) with potassium or sodium hydride in tetrahydrofuran or N,N-dimethylformamide or potassium hydroxide in dimethylsulfoxide and subsequent addition of the appropriately substituted fluorobenzene.

The 7β-methyl inhibitors described in Scheme 7 are prepared in a similar manner as that described above for the examples in Scheme 4, but using instead as starting material the 7β-methyl-16β-ol intermediate (63). Inversion of configuration at the 16-position to form (F) is effected using a Mitsunobu-based transformation as shown in Scheme 7. O-Alkylation to generate 16α-ethers, such as (77), is performed as already described above.
The inhibitors described in Scheme 8 are prepared as follows. Addition of methylmagnesium bromide in tetrahydrofuran to either ketone (52) or (62) affords the corresponding 16α-methyl-16β-alcohol (78) or (79). O-Alkylation or O-arylation is then carried out as described in the previous Schemes to afford the 16α-methyl-16β-ether derivatives, Compounds (80) and (81).

The inhibitors described in Scheme 9 are prepared as follows. The 7β-methyl-16α-alcohol (76) is converted into the 16β-thiol (H) by treatment with thiolacetic acid in the presence of diisopropyl azodicarboxylate (DIAD) and triphenylphosphine to give the intermediate 16β-thioacetate (G), which is then hydrolyzed under basic conditions to yield thiol (H). Alkylation is effected by generating the mercaptide anion with sodium hydride or potassium hydride in tertahydrofuran or N,N-dimethylformamide followed by addition of the appropriate alkyl halide. In this fashion are prepared Compounds 82-84. The corresponding sulfones, such as Compound 85, are obtained by treatment of the precursor thioethers (82-84) with an oxidizing agent, such as organic peracid or potassium peroxymonosulfate (OXONE), the latter in aqueous methanol.

The inhibitors described in Scheme 10 are prepared by the following synthetic pathways. The p-nitrophenoxy derivative (101) is reduced with Pd on carbon at room temperature in a H2 atmosphere to yield the p-amino-phenoxy derivative (102). The amine is then acylated with acetyl chloride in methylene chloride in the presence of pyridine to yield the p-acetylaminophenoxy derivative (103), or likewise treated with benzoyl chloride to yield the corresponding p-benzoylamino analog (104). Alternately, the amino compound (102) is treated with tosyl chloride to yield the p-tosylamino analog (105).

The inhibitors described in Scheme 11 are prepared as follows. The N-2,4-dimethoxybenzyl protected 16-alcohol (106) is treated with p-fluorochlorobenzene and potassium hydride in dimethylform-amide to yield the p-chlorophenoxy derivative (107), which is then treated with trifluoroacetic acid in methylene chloride to remove the N-2,4-dimethoxybenzyl protecting group to yield (108). This
is treated with hydrogen gas and a palladium on carbon catalyst in methanol to dechlorinate the phenyl ring to yield the phenoxy derivative (109). This compound is treated with methyl iodide and sodium hydride in dimethylformamide to methylate the ring nitrogen to yield (112). 

Alternately, (109) is treated with DDQ and BSTFA in toluene to introduce a double bond at the 1-position to yield (110). Utilizing the same reduction reaction scheme, the 1,2-dihydro androstane (108) yields the p-chloroandrost-1-ene (111). This is then methylated at the 1-position by treatment with methyl iodide, sodium hydride in dimethylformamide to yield (113).

The inhibitors described in Scheme 12 are prepared via similar reaction pathways as described in Scheme 11. The N-2,4-dimethoxybenzyl protected 16-alcohol (106) is treated with 3-methyl-3-chlorofluorobenzene and potassium hydride in dimethylformamide to yield the 4-methyl-3-chlorophenoxymethylenamine derivative (114), which is then treated with trifluoroacetic acid in methylene chloride to remove the N-2,4-dimethoxybenzyl protecting group to yield (115). This is treated with hydrogen gas and a palladium on carbon catalyst in methanol to dechlorinate the phenyl ring to yield the p-methylphenoxy derivative (116). This compound is treated with methyl iodide and sodium hydride in dimethylformamide to methylate the ring nitrogen to yield (118). 

Alternately, (116) is treated with DDQ and BSTFA in toluene to introduce a double bond at the 1-position to yield (117).

The inhibitors in Scheme 13 are prepared as follows. 

The starting 16-alcohol (76) is treated with methanesulfonic acid in pyridine containing DMAP to yield the mesylate (119). This in turn is treated with an appropriate thiophenol in anhydrous THF containing sodium hydride to yield the thiophenoxime (120), 4-chlorothiophenoxime (121), 4-fluorothiophenoxime (122), 4-methylthiophenoxime (127) and the 4-methoxy-thiophenoxime (124) derivatives. Treatment of the thiophenoxime (120) derivative with m-chloroperbenzoic acid in methylene chloride at 0°C for one hour yields the phenylsulfinyl derivative (125). Treatment of the phenylsulfinyl compound (125) under the same reaction conditions
prolonged however for three hours, yields the phenylsulfonyl derivative (126).

The inhibitors for Scheme 14 are prepared as follows. The 16-ketone (62) is treated with an appropriate arylmethyl diethylphosphonate under Wittig conditions using sodium hydride in DMF at 80-100°C to yield the corresponding 4-chlorobenzylidene (128), benzylidene (127) and 4-methylbenzylidene (129) analogs. These are reduced in ethanol under a hydrogen atmosphere using a 5% rhodium on carbon catalyst to yield the corresponding 4-chlorobenzyl (130) and 4-methylbenzyl (131) derivatives. The 3-pyridyl-methyl (132) analog is made in the same two step manner.

In another embodiment of this invention there is provided a combination method involving the use of a 5α-reductase 1 and/or 2 inhibitor, in combination with a retinoid agent, including but not limited to, e.g., tretinoin (all-trans-retinoic acid, RETIN A) and isotretinoin (13-cis-retinoic acid, ACCUTANE), and at least one agent selected from: an antibacterial, an anti-inflammatory, and a keratolytic, or combination thereof, in the prevention of acne vulgaris by topical and/or systemic administration.

The activity of the compounds as selective 5α-reductase 1 or 2 inhibitors, or dual inhibitors, can be determined by the following Biological assays:

**BIOLOGICAL ASSAYS**

15. **Preparation of Human prostatic and scalp 5α-reductases**

   Samples of human tissue were pulverized using a freezer mill and homogenized in 40 mM potassium phosphate, pH 6.5, 5 mM magnesium sulfate, 25 mM potassium chloride, 1 mM phenylmethylsulfonyl fluoride, 1 mM dithiothreitol (DTT) containing 0.25 M sucrose using a Potter-Elvehjem homogenizer. A crude nuclear pellet was prepared by centrifugation of the homogenate at 1,500xg for 15 min. The crude nuclear pellet was washed two times and resuspended in two volumes of buffer. Glycerol was added to the resuspended pellet to a final concentration of 20%. The enzyme suspension was frozen in aliquots at -80°C. The prostatic and scalp reductases were stable for at least 4 months when stored under these conditions.

**Cloned enzyme protocol:**

For IC₅₀ determinations, the test 5α-reductase 1 and 2 inhibitors were dissolved in ethanol and serially diluted to the appropriate concentration. The baculovirus-expressed recombinant type 1 5α-reductase was preincubated with inhibitor (0.1-1,000 nM) in 40 mM sodium phosphate, pH 7.0, 500 µM NADPH, 1 mM DTT and 1 mg/ml BSA for 18 h at 4°C. The reaction was initiated by the addition of [7-
3H]T (NEN, 20 Ci/mmol) and NADPH to a final concentration of 0.3 μM and NADPH and incubated at 37°C for 90 min. Similarly, baculovirus-expressed type 2 5α-reductase was preincubated with inhibitor (1-10,000 nM) in 40 mM sodium citrate, pH 5.5, 500 μM NADPH, 1mM DTT and 1 mg/ml BSA for 18 h at 4°C. The reaction was initiated by the addition of [7-3H]T (NEN, 20 Ci/mmol) and NADPH to a final concentration of 0.3 μM and 500 μM, respectively. The conversion of T to DHT was monitored using a radioflow detector following separation by reverse phase HPLC (Whatman RACII C18 column, 1ml/min 0.1% TFA in water:methanol (42:58); retention times T, 6.3 min, DHT, 9.7 min).

5α-reductase assay

The reaction mixture for the type 1 5α-reductase contained 40 mM potassium phosphate, pH 6.5, 5 μM [7-3H]-testosterone, 1 mM dithiothreitol and 500 μM NADPH in a final volume of 100 μl. The reaction mixture for the type 2 5α-reductase contained 40 mM sodium citrate, pH 5.5, 0.3 μM [7-3H]-testosterone, 1 mM dithiothreitol and 500 μM NADPH in a final volume of 100 μl. Typically, the assay was initiated by the addition of 50-100 μg prostatic homogenate or 75-200 μg scalp homogenate and incubated at 37°C. After 10-50 min the reaction was quenched by extraction with 250 μl of a mixture of 70% cyclohexane: 30% ethyl acetate containing 10 μg each DHT and T. The aqueous and organic layers were separated by centrifugation at 14,000 rpm in an Eppendorf microfuge. The organic layer was subjected to normal phase HPLC (10 cm Whatman partisil 5 silica column equilibrated in 1 ml/min 70% cyclohexane: 30% ethyl acetate; retention times: DHT, 6.8-7.2 min; androstanediol, 7.6-8.0 min; T, 9.1-9.7 min). The HPLC system consisted of a Waters Model 680 Gradient System equipped with a Hitachi Model 655A autosampler, Applied Biosystems Model 757 variable UV detector, and a Radiomatic Model A120 radioactivity analyzer. The conversion of T to DHT was monitored using the radioactivity flow detector by mixing the HPLC effluent with one volume of Flo Scint 1 (Radiomatic). Under the conditions described, the
production of DHT was linear for at least 25 min. The only steroids observed with the human prostate and scalp preparations were T, DHT and androstanediol.

Inhibition studies

Compounds were dissolved in 100% ethanol. IC50 values represent the concentration of inhibitor required to decrease enzyme activity to 50% of the control. IC50 values were determined using a 6 point titration where the concentration of the inhibitor was varied from 0.1 to 1000 nM.

A compound referred to herein as a 5α-reductase 1 inhibitor is a compound that shows inhibition of the 5α-reductase 1 isozyme in the above-described assay, having an IC50 value of about or under 600 nM.

A compound referred to herein as a 5α-reductase 2 inhibitor is a compound that shows inhibition of the 5α-reductase 2 isozyme in the above-described assay, having an IC50 value of about or under 600 nM.

A compound referred to herein as a dual 5α-reductase 1 and 2 inhibitor is a compound that shows inhibition of both the 5α-reductase 1 and 2 isozymes in the above-described assay, having an IC50 value for each of type 1 and type 2 of about or under 600 nM, and preferably 100 nm.

Fuzzy Rat Acne Model

Adult fuzzy rats are a variety of rat that has stunted hair growth, brown colored seborrhea covering their entire back skin and abnormally increased sebum production after puberty that has been demonstrated to be due to circulating androgens. 0.1, 0.05 and 0.025% solutions of a selected 5α-reductase inhibitor of interest are prepared in a vehicle of propylene glycol, isopropanol, isopropyl myristate and water (50/30/2/18%), and is topically applied onto the backs of adult male fuzzy rats, 0.2 ml per animal daily for 4 weeks. Controls receive the vehicle alone and 5 of them are castrated. After 2 weeks seborrhea will be dose-dependently depleted and after 4 weeks bromodeoxyuridine (BrdU, 200 mg/kg) is intraperitoneally injected 2 hours before sacrifice.
The skin tissues are incubated with EDTA (20 mM) in phosphate buffer, 1.5 hours at 37°C. The pilo-sebaceous unit attached to the epidermis is striped from the dermis and fixed with formalin for immuno-staining of BrdU. DNA synthesis cells showing a BrdU-positive nucleus are located in the outer glandular border. The number of S-phase cells per lobe is determined with a micro-image apparatus. Using formalin fixed skin, frozen serial sections are stained with 1% osmium and the size of the lobes is measured. A positive inhibitor of skin 5α-reductase will induce suppression of sebum production by inhibiting the rate of glandular cell turnover, and showing reduced lobular size.

Representative compounds of Formulas I and II were tested in the above described inhibition assay for 5α-reductase type 1 and type 2 inhibition. For the inhibition of 5α-reductase type 1, the compounds have IC50 values lower than 600 nM, with the majority of compounds in general having IC50 values ranging from about 0.3 nM to about 200 nM. For the inhibition of 5α-reductase type 2, the same compounds have IC50 values greater than about 155 nM, with the majority of compounds having IC50 values greater than 1000 nM. The compounds in general have at least a 2-fold greater selectivity for inhibition of 5α-reductase type 1 over type 2, with the majority of the compounds having a 10-fold or greater selectivity for inhibition of 5α-reductase type 1 over type 2. These results demonstrate the utility of the compounds of the instant invention for the treatment of hyperandrogenic conditions.

A compound referred to herein as a 5α-reductase 1 inhibitor is a compound that shows inhibition of the 5α-reductase 1 isozyme in the above-described assay.

A compound referred to herein as a 5α-reductase 2 inhibitor is a compound that shows inhibition of the 5α-reductase 2 isozyme in the above-described assay.

The 5 alpha reductase 1 or 2 inhibitor, or mixture thereof,
retinoid agent, anti-inflammatory, keratolytic and anti-inflammatory can
each be administered orally, systemically or topically, as separate or
concurrent dosage forms, or together as one formulation. A useful
protocol is the use of the anti-inflammatory, keratolytic and antibacterial
topically and the use of the 5 alpha reductase 1 and/or 2 inhibitor orally.
For combination treatment where the combination agents are in separate
dosage formulations, they can be administered concomitantly, or they
each can be administered separately at staggered times.

For example, a compound of Formula I, e.g., 4,7-beta-
dimethyl-4-aza-5-alpha-cholestan-3-one, and retinoid, i.e., tretinoin, can
be administered together in a single topical dosage formulation, or each
active agent can be separately administered in a particular dosage
formulation, e.g., as a separate oral (5α-reductase inhibitor) and topical
(retinoid) dosage formulations, or a topical dosage formulation of the
retinoid in combination with an oral dosage formulation of a compound
of Formula I. See, e.g., U.S. Patent No.'s 4,377,584 and 4,760,071 which
describe dosages and formulations for 5α-reductase inhibitors.

One useful combination is tretinoin, erythromycin and a 5α-
reductase 1 inhibitor, e.g., 3-oxo-4-aza-4,7β-dimethyl-16β-(4-
chlorophenoxy)-5α-androstan.

In the methods described above, the daily dosage of the 5
alpha reductase 1 inhibitor compounds of Formula I and II may be varied
over a wide range from 0.1 mg to 1,000 mg per adult human/per day. An
effective amount of one of the novel compounds of this invention is
ordinarily from about 0.002 mgs/kg to 50 mgs./kg of body weight per
day, and more particularly the range is from about 0.01 mgs/kg to 7
mgs/kg of body weight per day.

The daily dosage of the tretinoin is topically administered in
a 0.025% to 0.1% by weight cream or gel.

The daily dosage of the isotretinoin is systemically from
about 0.01 mg/kg to 2 mg/kg per adult human/per day.

The daily dosage of the keratolytic is topically administered
in a 0.025% to 0.1% by weight cream or gel.

The daily dosage of the antibacterial systemically is from
about one mg to 2000 mg per adult human/per day, and more particularly
from about 200 mg to 1000 mg per adult human/per day. The daily
amount of antibacterial is from 1 mgs/kg to 50 mgs/kg of human body weight daily.

The daily dosage of the anti-inflammatory topically or systemically is from about 0.01 mg to 2000 mg per adult human/per day, and more particularly from about one mg to 1000 mg per adult human/per day. The daily amount of anti-inflammatory is from 0.02 mgs/kg to 40 mgs/kg of human body weight daily.

For mild to moderate acne, topical daily therapy is generally indicated to avoid the side effects of the more rigorous systemic therapy with its attendant side effects. For moderate to severe acne, systemic therapy is generally used, which can also be combined with topical therapy, where warranted. Duration of therapy, depending on the severity, can last for 3-6 months, and in some cases, for several years.

Advantageously, the combination of the present invention may be administered in a single daily dose, or the total daily dosage may be administered in divided doses of two, three or four times daily. The combination for the present invention can also be administered in intranasal form via topical use of suitable intranasal vehicles, or via transdermal routes, using those forms of transdermal skin patches well known to those of ordinary skill in that art. To be administered in the form of a transdermal delivery system, the dosage administration will, of course, be continuous rather than intermittent throughout the dosage regimen.

For the treatment of acne vulgaris, the compounds of the instant invention can also be combined with a therapeutically effective amount of a 5α-reductase 2 inhibitor, such as finasteride, in a single oral, systemic, or parenteral pharmaceutical dosage formulation. Also, for the skin and scalp related disorders of acne vulgaris, the compounds of the instant invention and a 5α-reductase 2 inhibitor can be formulated for topical administration. Alternatively, a combined therapy can be employed wherein the compound of Formula I and the 5α-reductase 2 inhibitor are administered in separate oral, systemic, parenteral or topical dosage formulations. For example, a compound of Formula I and finasteride can be administered in a single oral or topical dosage
formulation, or each active agent can be administered in a separate dosage formulation, e.g., in separate oral dosage formulations, or an oral dosage formulation of finasteride in combination with a topical dosage formulation of a compound of Formula I. See, e.g., U.S. Patent No.'s 4,377,584 and 4,760,071 which describe dosages and formulations for 5α-reductase inhibitors. Where the active agents are in separate dosage formulations, they can be administered concomitantly, or they each can be administered at separately staggered times.

Other 5α-reductase 2 inhibitors, both steroidal and non-steroidal, which can be employed in the instant invention include (listed by company of development and publications/patents containing the pertinent disclosure):

The dosage regimen utilizing the compounds of the present invention is selected in accordance with a variety of factors including type, species, age, weight, sex and medical condition of the patient; the severity of the condition to be treated; the route of administration; the renal and hepatic function of the patient; and the particular compound thereof employed. A physician or veterinarian of ordinary skill can readily determine and prescribe the effective amount of the drug required to prevent, counter, arrest or reverse the progress of the condition. Optimal precision in achieving concentration of drug within the range that yields efficacy without toxicity requires a regimen based on the kinetics of the drug's availability to target sites. This involves a consideration of the distribution, equilibrium, and elimination of a drug.

In the methods of the present invention, the combination of 5 alpha reductase 1 and/or 2 inhibitor, a retinoid, e.g., tretinoin/ isotretinoin, antibacterial, keratolytic and anti-inflammatory, herein described in detail, are typically administered in admixture with suitable pharmaceutical diluents, excipients or carriers (collectively referred to herein as "carrier" materials) suitably selected with respect to the intended form of administration, that is, oral tablets, capsules, elixirs, syrups and the like, and consistent with conventional pharmaceutical practices.

Oral administration can be conducted in the form of a tablet or capsule, the combination drug components can be combined with an oral, non-toxic pharmaceutically acceptable inert carrier such as ethanol.
glycerol, water and the like. Capsules containing the combination agents of this invention can be prepared by mixing combination agents of the present invention with lactose and magnesium stearate, calcium stearate, starch, talc or other carriers, and placing the mixture in gelatin capsule.

Tablets may be prepared by mixing the combination ingredients with conventional tableting ingredients such as calcium phosphate, lactose, corn starch or magnesium stearate. Moreover, when desired or necessary, suitable binders, lubricants, disintegrating agents and coloring agents can also be incorporated into the mixture. Suitable binders include starch, gelatin, natural sugars such as glucose or beta-lactose, corn sweeteners, natural and synthetic gums such as acacia, tragacanth or sodium alginate, carboxymethylcellulose, polyethylene glycol, waxes and the like. Lubricants used in these dosage forms include sodium oleate, sodium stearate, magnesium stearate, sodium benzoate, sodium acetate, sodium chloride and the like. Disintegrators include, without limitation, starch, methyl cellulose, agar, bentonite, xanthan gum and the like. The oral compositions can be provided in the form of scored or unscored tablets containing 0.1, 0.5, 1.0, 2.5, 5.0, 10.0, 15.0, 25.0, 50.0, and 100.0 milligrams of the active ingredients, the 5 alpha reductase 1 inhibitor, tretinoin/ isotretinoin, anti-inflammatory, keratolytic, antibacterial. The symptomatic adjustment of the dosage to the patient to be treated.

Topical pharmaceutical compositions may be, e.g., in the form of a solution, cream, ointment, gel, lotion, shampoo or aerosol formulation adapted for application to the skin. Topical pharmaceutical compositions useful in the method of treatment of the present invention may include about 0.001% to 15% by weight each of 5 alpha reductase 1 inhibitor compound, anti-inflammatory, keratolytic, antibacterial in admixture with a pharmaceutically acceptable carrier. Topical preparations containing the combination active drug components can be admixed with a variety of carrier materials well known in the art, such as, e.g., alcohols, aloe vera gel, allantoin, glycerine, vitamin A and E oils, mineral oil, PPG2 myristyl propionate, and the like, to form, e.g., alcoholic solutions, topical cleansers, cleansing creams, skin gels, skin
lotions, and shampoos in cream or gel formulations. See, e.g., EP 0 285 382.

Liquid forms of the combination can also be administered in intravenous (both bolus and infusion), intraperitoneal, subcutaneous, topical with or without occlusion, or intramuscular form, all using forms well known to those of ordinary skill in the pharmaceutical arts. The liquid forms can contain suitably flavored suspending or dispersing agents such as the synthetic and natural gums, for example, tragacanth, acacia, methyl-cellulose and the like. Other dispersing agents which may be employed include glycerin and the like. For parenteral administration, sterile suspensions and solutions are desired. Isotonic preparations which generally contain suitable preservatives are employed when intravenous administration is desired.

The combination agents of the present invention can also be administered in the form of liposome delivery systems, such as small unilamellar vesicles, large unilamellar vesicles and multilamellar vesicles. Liposomes can be formed from a variety of phospholipids, such as cholesterol, stearylamine or phosphatidylcholines.

Compounds of Structures I and II, of the present invention, can also be delivered by the use of monoclonal antibodies as individual carriers to which the compound molecules are coupled. The compounds of the present invention may also be coupled with soluble polymers as targetable drug carriers. Such polymers can include polyvinylpyrrolidone, pyran copolymer, polyhydroxypropylmethacrylamidephenol, polyhydroxyethylaspartamidephenol, or polyethyleneoxidepolylysine substituted with palmitoyl residues. Furthermore, the compounds of the present invention may be coupled to a class of biodegradable polymers useful in achieving controlled release of a drug, for example, polylactic acid, polypepsilon caprolactone, polyhydroxy butyric acid, polyorthoesters, polyacetals, polydihydropyranes, polycyanoacrylates and cross-linked or amphipathic block copolymers of hydrogels.

The following examples are provided to further illustrate details for the preparation of the compounds of the present invention. The examples are not intended to be limitations on the scope of the
instant invention in any way, and they should not be so construed. Furthermore, the compounds described in the following examples are not to be construed as forming the only genus that is considered as the invention, and any combination of the compounds or their moieties may itself form a genus. Those skilled in the art will readily understand that known variations of the conditions and processes of the following preparative procedures can be used to prepare these compounds. All temperatures are in degrees Celsius unless noted otherwise.

The contents were cooled, diluted with ethyl acetate, washed with aqueous sodium carbonate, aqueous sodium bisulfite, brine, dried over magnesium sulfate and concentrated to yield an oil. The crude compound was purified by preparative TLC on silica gel, eluting with 3:1 CHCl₃/acetone to yield pure 49, whose proton NMR confirmed the assigned structure.

The following Table lists the unique proton NMR values (400 MHz in CDCl₃) for each compound. The data are reported as: s = singlet, d = doublet, m = multiplet, J = coupling constant. The absorption values are given in delta (δ) scale with a reference point signal from tetramethylsilane, and are illustrated for the C-18, C-19 and C-21 angular ring methyl protons and protons associated with unique portions of the molecule.

The numbering of the 4-aza steroid is given by the following structure:

**Examples for Formula II**

The starting material 4-aza-4-methyl-5α-androstan-3,17-dione (Compound A in Scheme 1 above, for Formula II) can be made according to the methods described in Rasmusson, *et al.*, *J. Med. Chem.*, 27, p. 1690-1701 (1984). The starting material 4-aza-4,7β-dimethyl-5α-androstan-3,17-dione can be synthesized according to the procedure described in Example 33, below.
EXAMPLE 33

4-Aza-4-methyl-5α-androstan-3,16-dione

5 Step 1: 4-aza-4-methyl-5α-androstan-3,17-dione-16-oxime
To 2-methyl-2-propanol (14 mL) in a round-bottom flask under a stream of nitrogen gas was added potassium tert-butoxide (740 mg, 6.59 mmol). After complete solution was achieved, 4-aza-4-methyl-5α-androstan-3,17-dione (1.0 g, 3.30 mmol) was added and stirring was continued for 1 hour affording a gold-colored solution. To the reaction mixture was added dropwise with stirring isoamyl nitrite (0.884 mL, 6.58 mmol), and stirring was continued overnight at room temperature affording a deep-orange solution. The mixture was then diluted with an equal volume of water and acidified to pH ~2 with 2 N hydrochloric acid. Diethyl ether was added, and the solid that formed was filtered, washed with ether, and dried in vacuo, to yield the title compound.

Step 2: 4-aza-4-methyl-5α-androstan-3-one-16-oxime (B)
To a mixture of 4-aza-4-methyl-5α-androstan-3,17-dione-16-oxime (596 mg, 1.79 mmol) in ethylene glycol (5 mL) were added 98% hydrazine (57 μL, 1.74 mmol) and powdered potassium hydroxide (568 mg, 10.12 mmol). The mixture was heated for 16 h at 140°. cooled, and neutralized with 2N hydrochloric acid. INTERNATIONAL SEARCH REPORT

Box I  Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This international report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. [ ] Claims Nos.:  
   because they relate to subject matter not required to be searched by this Authority, namely:

2. [ ] Claims Nos.:  
   because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:

3. [ ] Claims Nos.:  
   because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II  Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

   Please See Extra Sheet.

1. [ ] As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.

2. [ ] As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.

3. [ ] As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:

4. [x] No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.: 1-20, 26-33

Remark on Protest  
[ ] The additional search fees were accompanied by the applicant’s protest.  
[ ] No protest accompanied the payment of additional search fees.

Form PCT/ISA/210 (continuation of first sheet(1))(July 1992)
BOX II. OBSERVATIONS WHERE UNITY OF INVENTION WAS LACKING
This ISA found multiple inventions as follows:

This application contains the following inventions or groups of inventions which are not so linked as to form a single inventive concept under PCT Rule 13.1. In order for all inventions to be examined, the appropriate additional examination fees must be paid.

Group I, claims 1-20 and 26-33, drawn to a method of treating acne comprising the step of administering to a person in need thereof a therapeutically effective amount of a 5-alpha-reductase inhibitor, a retinoid agent, and an antibacterial agent.

Group II, claims 1-17, 21, 22, and 26-33, drawn to a method of treating acne comprising the step of administering to a person in need thereof a therapeutically effective amount of a 5-alpha-reductase inhibitor, a retinoid agent, and a keratolytic agent.

Group III, claims 1-17 and 23-33, drawn to a method of treating acne comprising the step of administering to a person in need thereof a therapeutically effective amount of a 5-alpha-reductase inhibitor, a retinoid agent, and an anti-inflammatory agent.

The inventions listed as Groups I-III do not relate to a single inventive concept under PCT Rule 13.1 because, under PCT Rule 13.2, they lack the same or corresponding special technical features for the following reasons: each group is drawn to separate and distinct classes of therapeutic agents (i.e., antibacterial, keratolytic, and anti-inflammatory agents), which are each known to treat different conditions by different mechanisms.
