(54) **Titre : MOTEUR COMBINE CYCLIQUE**

(54) **Title: COMPOUND CYCLE ENGINE**

(57) **Abrégé/Abstract:**

A compound cycle engine having at least one rotary unit defining an internal combustion engine, a velocity turbine in proximity of each unit, and a turbocharger is discussed. The exhaust port of each rotary unit is in fluid communication with the flowpath of the velocity turbine upstream of its rotor. The rotors of the velocity turbine and of each rotary unit drive a common load. The outlet of the compressor of the turbocharger is in fluid communication with the inlet port of each rotary unit, and the inlet of the pressure turbine of the turbocharger is in fluid communication with the flowpath of the velocity turbine downstream of its rotor. A method of compounding at least one rotary engine is also discussed.

ABSTRACT

A compound cycle engine having at least one rotary unit defining an internal combustion engine, a velocity turbine in proximity of each unit, and a turbocharger is discussed. The exhaust port of each rotary unit is in fluid communication with the flowpath of the velocity turbine upstream of its rotor. The rotors of the velocity turbine and of each rotary unit drive a common load. The outlet of the compressor of the turbocharger is in fluid communication with the inlet port of each rotary unit, and the inlet of the pressure turbine of the turbocharger is in fluid communication with the flowpath of the velocity turbine downstream of its rotor. A method of compounding at least one rotary engine is also discussed.

COMPOUND CYCLE ENGINE

TECHNICAL FIELD

[0001] The application relates generally to compound cycle engines and, more particularly, to such compound cycle engines including one or more rotary combustion engine(s).

BACKGROUND OF THE ART

[0002] Some compound cycle engines include a rotary engine turbocharged and compounded by a turbine located downstream of the turbocharger turbine. However, known compounded rotary engine arrangements typically have limited available power for turbo compounding and/or limited performances, for example on start-up before the turbocharger is running.

SUMMARY

[0003] In one aspect, there is provided a compound cycle engine comprising: at least one rotary unit with each unit defining an internal combustion engine including a rotor sealingly and rotationally received within a respective housing, each housing defining an inlet port and an exhaust port; a velocity turbine in proximity of each unit and including a rotor supporting a circumferential array of blades extending across a flowpath, the exhaust port of each housing being in fluid communication with the flowpath upstream of the rotor of the velocity turbine, the rotor of the velocity turbine and the rotor of each unit being in driving engagement with a common load; and a turbocharger including a compressor and a pressure turbine in driving engagement through a same shaft, an outlet of the compressor being in fluid communication with the inlet port of each housing, and an inlet of the pressure turbine being in fluid communication with the flowpath downstream of the rotor of the velocity turbine.

[0004] In another aspect, there is provided a compound cycle engine comprising: at least one rotary engine having a rotor sealingly and rotationally received within a respective housing having an inlet port and an exhaust port, the rotor of each rotary engine being drivingly engaged to a common load; a velocity turbine in proximity of each rotary engine and having a rotor drivingly engaged to the common load; a respective exhaust pipe providing fluid communication between each exhaust port and the velocity turbine upstream of the rotor thereof; a turbocharger including a

compressor and a pressure turbine drivingly engaged to a same shaft; an inlet duct providing fluid communication between an outlet of the compressor and the inlet port of each rotary engine; and a turbine pipe providing fluid communication between an outlet of the velocity turbine and an inlet of the pressure turbine.

[0005] In a further aspect, there is provided a method of compounding at least one rotary engine, the method comprising: drivingly engaging a pressure turbine and a compressor in a turbocharger; defining a fluid communication between an outlet of the compressor and an inlet port of each rotary engine; defining a fluid communication between an exhaust port of each rotary engine and an inlet of a velocity turbine, including directing the fluid communication onto blades of a rotor of the velocity turbine; defining a fluid communication between an outlet of the velocity turbine and an inlet of the pressure turbine of the turbocharger; and drivingly engaging each rotary engine and the velocity turbine to a common load.

DESCRIPTION OF THE DRAWINGS

[0006] Reference is now made to the accompanying figures in which:

[0007] Fig. 1 is a block diagram of a compound cycle engine according to a particular embodiment;

[0008] Fig. 2 is a cross-sectional view of a Wankel engine which can be used in a compound cycle engine such as shown in Fig. 1, according to a particular embodiment;

[0009] Fig. 3 is a schematic representation of the compound cycle engine of Fig. 1 according to a particular embodiment;

[0010] Fig. 4 is a schematic tridimensional view of a compound cycle engine such as shown in Fig. 3 according to a particular embodiment; and

[0011] Fig. 5 is a block diagram of a compound cycle engine according to another embodiment.

DETAILED DESCRIPTION

[0012] Referring now to Fig. 1, a compound cycle engine 10 is schematically shown. The compound cycle engine 10 includes one or more rotary units 12, each unit 12 being defined by a rotary internal combustion engine having a rotor sealingly engaged in a respective housing. The rotary unit(s) 12 drive a common load. In the embodiment shown, the common load includes an output shaft 16 which may be for

example connected to a propeller through a reduction gearbox (not shown) and to which the rotor of each unit 12 is engaged.

[0013] The compound cycle engine 10 also includes a turbocharger 18, formed by a compressor 20 and a pressure turbine 22 which are drivingly interconnected by a shaft 24. The compressor 20 and the turbine 22 may each be a single-stage device or a multiple-stage device with a single shaft or split on multiple independent shafts in parallel or in series, and may be a centrifugal or axial device. In the embodiment shown, the shaft 24 of the turbocharger 18 rotates independently of the common load. The compressor 20 of the turbocharger 18 compresses the air before it enters the unit(s) 12.

[0014] The rotary unit(s) 12 form the core of the compound cycle engine 10 and each provide an exhaust flow in the form of exhaust pulses. The exhaust flow from the unit(s) 12 is supplied to a power turbine 26 in fluid communication therewith, also driving the common load. The power turbine 26 is a velocity type turbine, also known as an impulse turbine, and could be an axial, radial or mixed flow turbine.

[0015] In a velocity turbine, the fluid is deflected without a significant pressure drop in the blade passages. Velocity turbines thus differ from pressure turbines in that in the pressure drop occurring over the rotor in a pressure turbine is not present in a velocity turbine. Velocity turbines typically have blades with different cross-sections than pressure turbines; for example, blades of pressure turbines usually have a change in flow area as the working fluid circulates therethrough, while blades of velocity turbines usually have a constant flow area; blades of pressure turbines are usually not symmetrical about the plane of the rotating disc, while blades of velocity turbines usually are. Each blade of the velocity turbine 26 thus forms a bucket pushed by the exhaust flow. The rotor of the power turbine 26 is rotated by the forces created on the blades by the impingement against them of the exhaust pulses. As such, the kinetic energy provided by each exhaust pulse is used to drive the rotor of the power turbine 26 while imposing minimum back pressure on the rotary unit(s) 12.

[0016] The power turbine 26 is connected to the output shaft 16 through an appropriate type of transmission 28, for example a planetary, star, offset or angular gear system. The outlet of the power turbine 26 is in fluid communication with an inlet of the turbocharger turbine 22. Energy is extracted from the exhaust gas exiting

the power turbine 26 by the turbocharger turbine 22 to drive the compressor 20 via the connecting shaft 24.

[0017] Although not shown, the air may optionally circulate through an intercooler between the compressor 20 and the unit(s) 12, and the compound cycle engine 10 also includes a cooling system, including for example a circulation system for a coolant (e.g. water-ethylene, oil, air) to cool the housing of each unit 12, an oil coolant for the internal mechanical parts of the unit(s) 12, one or more coolant heat exchangers, etc.

[0018] The fuel injector(s) of each unit 12, which in a particular embodiment are common rail fuel injectors, communicate with a source 30 of Heavy fuel (e.g. diesel, kerosene (jet fuel), equivalent biofuel), and deliver the heavy fuel into the unit(s) 12 such that the combustion chamber is stratified with a rich fuel-air mixture near the ignition source and a leaner mixture elsewhere.

[0019] In a particular embodiment each unit 12 is a Wankel engine. Referring to Fig. 2, an exemplary embodiment of a Wankel engine is shown; it is understood that the configuration of the unit(s) 12 used in the compound cycle engine 10, e.g. placement of ports, number and placement of seals, etc., may vary from that of the embodiment shown; each unit 12 may be defined by a rotary engine other than a Wankel engine.

[0020] As shown in Fig. 2, in a particular embodiment, each unit 12 comprises a housing 32 defining a rotor cavity with a profile defining two lobes, which is preferably an epitrochoid. A rotor 34 is received within the rotor cavity. The rotor defines three circumferentially-spaced apex portions 36, and a generally triangular profile with outwardly arched sides. The apex portions 36 are in sealing engagement with the inner surface of a peripheral wall 38 of the housing 32 to form three working chambers 40 between the rotor 34 and the housing 32.

[0021] The rotor 34 is engaged to an eccentric portion 42 of the output shaft 16 to perform orbital revolutions within the stator cavity. The output shaft 16 performs three rotations for each orbital revolution of the rotor 34. The geometrical axis 44 of the rotor 34 is offset from and parallel to the axis 46 of the housing 32. During each orbital revolution, each chamber 40 varies in volume and moves around the stator cavity to undergo the four phases of intake, compression, expansion and exhaust.

[0022] An intake port 48 is provided through the peripheral wall 38 for admitting compressed air into one of the working chambers 40. An exhaust port 50 is also provided through the peripheral wall 38 for discharge of the exhaust gases from the working chambers 40. Passages 52 for a spark plug or other ignition mechanism, as well as for one or more fuel injectors (not shown) are also provided through the peripheral wall 38. Alternately, the intake port 48, the exhaust port 50 and/or the passages 52 may be provided through an end or side wall 54 of the housing.

[0023] For efficient operation the working chambers 40 are sealed, for example by spring-loaded apex seals 56 extending from the rotor 34 to engage the peripheral wall 38, and spring-loaded face or gas seals 58 and end or corner seals 60 extending from the rotor 34 to engage the end walls 54. The rotor 34 also includes at least one spring-loaded oil seal ring 62 biased against the end wall 54 around the bearing for the rotor 34 on the shaft eccentric portion 42.

[0024] Each Wankel engine provides an exhaust flow in the form of a relatively long exhaust pulse; for example, in a particular embodiment, each Wankel engine has one explosion per 360° of rotation of the output shaft, with the exhaust port remaining open for about 270° of that rotation, thus providing for a pulse duty cycle of about 75%. By contrast, a piston of a reciprocating 4-stroke piston engine typically has one explosion per 720° of rotation of the output shaft with the exhaust port remaining open for about 180° of that rotation, thus providing a pulse duty cycle of 25%. In a particular embodiment, the relatively long exhaust pulse of the Wankel engine may facilitate driving of the velocity power turbine 26.

[0025] The pressure ratios across a compound cycle engine with one or more rotary engines or units can be defined by:

$$P_C = P_R P_{PT} P_{TT}$$

where P_C is the pressure ratio for the turbocharger compressor, P_R is the inlet to outlet pressure ratio of the rotary engines, P_{PT} is the pressure ratio for the power/compound turbine, and P_{TT} is the pressure ratio for the turbocharger turbine.

[0026] The inventors have found that in prior art compound engines including one or more rotary engines where the power turbine is a pressure turbine located downstream of the turbocharger turbine, and where each rotary engine has equal volumetric expansion and compression ratios, the relatively high volumetric compression ratio of the rotary engine(s) typically results in a relatively low possible

pressure ratio for the compressor of the turbocharger (P_C), as limited by the peak pressure capability of the rotary engine(s). As such, the pressure ratio across the turbines ($P_{PT}P_{TT}$) is limited, which limits the power available for the power turbine.

[0027] In some compound engines, such as shown in U.S. 7,775,044 issued August 17, 2010 and incorporated by reference herein, the volumetric compression ratio of each rotary engine is smaller than its expansion ratio. The lower volumetric compression ratio typically results in a larger possible pressure ratio for the compressor of the turbocharger (P_C), which in turn increases the pressure ratio across the turbines ($P_{PT}P_{TT}$). However, the lower volumetric compression ratio usually leads to an inlet to outlet pressure ratio of the rotary engine(s) which is reduced P_R , which may increase back pressure and thermal loads on the rotary engine(s) because of the increased difficulty in purging the exhaust gases. Such a configuration also generally provides for a low compression on the rotary engine on start-up before the turbocharger is running, which may limit performances of the compound cycle engine.

[0028] By contrast, in the compound cycle engine 10, the pressure ratio P_{PT} across the power turbine 26 is about 1 since it is a velocity turbine. As such, a same pressure ratio for the compressor P_C (to comply with the peak pressure capability) and a same inlet to outlet pressure ratio of the rotary unit(s) P_R (to minimize backpressure and thermal loading on each rotary unit) allow for the pressure ratio P_{TT} available for the turbine 22 of the turbocharger 18 to be greater than with a compound cycle engine in which the power turbine is a pressure turbine, i.e. with a pressure ratio P_{PT} greater than 1. Thus, the use of a velocity turbine as the power turbine 26 may allow for an increase of the power available to the turbo compounding.

[0029] In addition, the volumetric compression ratio of the rotary unit(s) 12 does not need to be reduced to achieve this increase in power available for the turbine 22 of the turbocharger 18. As such, in a particular embodiment, the volumetric efficiency of each rotary unit may be maximized and its thermal loads minimized, and the performances of the compound cycle engine 10 at start-up are not compromised by the increase of available power.

[0030] Also, the use of a velocity turbine as the power turbine 26 eliminates the need for the large volume exhaust collector typically required between the rotary

engine(s) and a pressure power turbine. This allows for the power turbine 26 to be located upstream of the compound turbine 22 instead of downstream thereof.

[0031] In a particular embodiment which may be particularly but not exclusively suitable for low altitude, each rotary unit 12 is a Wankel engine with a volumetric compression ratio of from 6:1 to 8:1. The power recovery of the velocity turbine 26 may be maximized by having the exhaust gas temperatures at the material limit, and as such is suitable for such relatively low volumetric compression ratios, which may help increase the power density of the Wankel engine and may also improve combustion at high speed and of heavy fuel.

[0032] Referring to Figs. 3-4, a compound cycle engine 10 according to a particular embodiment is schematically shown. In this embodiment, two rotary units 12 in the form of Wankel engines are included, with the two eccentric portions 42 of the output shaft 16 being angularly offset at 180° from one another for balancing of the compound cycle engine 10. In other embodiments, more or less rotary engines may be provided.

[0033] The rotor blades 64 of the velocity power turbine 26 extend across an annular flowpath 66. In the embodiment shown, the rotor of the power turbine 26 is an axial rotor and the flowpath 66 extends axially. A respective exhaust pipe 68 extends from the exhaust port 50 (see also Fig. 2) of each unit 12 to the flowpath 66, upstream of the rotor blades 64. The exhaust pipes 68 extend independently from one another, and their length are minimized to maximize use of the exhaust pulse kinetic energy to drive the power turbine 26. The flowpath 66 and/or the outlet of each exhaust pipe 68 are shaped to direct the exhaust pulses onto the blades 64 to allow the exhaust pulses to drive rotation of the rotor of the power turbine 26. As can be seen more clearly from Fig. 4, each exhaust pipe 68 communicates with the flowpath 66 at a different location around the circumference of the power turbine 26.

[0034] A pipe 70 extends from an outlet of the compressor 20, and splits into two inlet pipes 72, each connected to the intake port 48 (see also Fig. 2) of the respective rotary unit 12. In this embodiment, the compressor 20 includes a single radial impeller 74. Alternately, the compressor 20 may include one or more rotors, with radial, axial or mixed flow blades.

[0035] In the embodiment shown, the transmission 28 of the power turbine 26 includes a sun gear 76 attached on the shaft of the rotor of the power turbine 26, and an array of planet gears 78 meshed with the sun gear 76. The planet gears 78

are mounted on a rotating carrier which is drivingly engaged to the output shaft 16. The planet gears 78 are meshed with a stationary ring gear 79. In another embodiment, the planet gears 78 are mounted on a stationary carrier, and are meshed with a ring gear drivingly engaged to the output shaft 16. The speed reduction ratio of the transmission 28 may be selected to optimize operation of the velocity power turbine 26 and of the rotary units 12.

[0036] A turbine pipe 80 extends from the flowpath 66 downstream of the rotor blades 64 to the inlet of the turbocharger turbine 22. In this embodiment, the turbocharger turbine 22 includes a single radial impeller 82. Alternately, the turbocharger turbine 22 may include one or more rotors, with radial, axial or mixed flow blades.

[0037] The turbocharger shaft 24 extends along a different axis than that of the output shaft 16. In the particular embodiment shown in Fig. 4, the turbocharger shaft 24 extends transverse to the output shaft 16. The turbocharger shaft 24 may additionally be connected to a different load than that of the output shaft 16, through a gearbox if necessary.

[0038] Referring to Fig. 5, a compound cycle engine 110 according to another embodiment is schematically shown, where elements similar to those of the previously described compound cycle engine 10 are identified by the same reference numerals and will not be further described therein. In this embodiment, the turbocharger 118 is defined coaxially with the output shaft 16. The compressor 120 is connected to the output shaft 16 through an appropriate type of transmission 128, for example a planetary or star gear system. The pressure turbine 122 of the turbocharger 118 is connected to the velocity power turbine 26 to rotate together therewith, or else connected to the output shaft 16 through an appropriate type of transmission (not shown).

[0039] In another embodiment which is not shown, the turbocharger and rotary unit(s) are coaxial, but the output shaft and turbocharger shaft rotate independently from one another, for example with the output shaft being hollow and surrounding the turbocharger shaft which extends therethrough.

[0040] Although not shown, in all embodiments, variable geometry elements such as inlet guide vanes, blow-off valves, waste gates, variable turbine nozzles, etc. may be used to obtain desired system operability.

[0041] Although not shown, the velocity power turbine 26 may be mounted in an offset manner rather than co-axially with the rotary units 12. The power turbine 26 may be drivingly engaged to the output shaft through an angular, for example perpendicular, transmission system, for example including a gearbox and a tower shaft.

[0042] The above description is meant to be exemplary only, and one skilled in the art will recognize that changes may be made to the embodiments described without departing from the scope of the invention disclosed. Modifications which fall within the scope of the present invention will be apparent to those skilled in the art, in light of a review of this disclosure, and such modifications are intended to fall within the appended claims.

CLAIMS

1. A method of compounding at least one rotary engine, the method comprising:
 - drivingly engaging a second turbine and a compressor in a turbocharger;
 - forming a fluid communication between an outlet of the compressor and an inlet port of each rotary engine;
 - forming a fluid communication between an exhaust port of each rotary engine and an inlet of a first turbine, including directing exhaust pulses from the rotary engine onto blades of a rotor of the first turbine;
 - driving a rotation of the blades of the rotor of the first turbine using kinetic energy imparted by impingement of the exhaust pulses against the blades;
 - forming a fluid communication between an outlet of the first turbine and an inlet of the second turbine of the turbocharger; and
 - drivingly engaging each rotary engine and the first turbine to a common shaft; wherein the first turbine is configured as a velocity turbine and the second turbine is configured as a pressure turbine, the first turbine having a pressure ratio smaller than that of the second turbine.
2. The method as defined in claim 1, further comprising providing fluid communication between a source of heavy fuel and each rotary engine.
3. The method as defined in claim 1, wherein each rotary engine has a volumetric compression ratio within a range defined from 6:1 to 8:1.
4. The method as defined in claim 1, wherein the first turbine has a pressure ratio of about 1.
5. A compound cycle engine comprising:
 - at least one rotary unit with each rotary unit defining an internal combustion engine including a rotor sealingly and rotationally received within a respective housing, each housing defining an inlet port through which combustion air is admitted and an exhaust port through which exhaust pulses are expelled;

a first turbine in proximity of each rotary unit and including a first turbine rotor supporting a circumferential array of blades extending across a flowpath, the exhaust port of each housing being in fluid communication with the flowpath upstream of the first turbine rotor, the first turbine rotor and the rotor of each rotary unit being in driving engagement with a common shaft; and

a turbocharger including a compressor and a second turbine in driving engagement with one another, an outlet of the compressor being in fluid communication with the inlet port of each housing, and an inlet of the second turbine being in fluid communication with the flowpath downstream of the first turbine rotor;

wherein the first turbine is configured as a velocity turbine and the second turbine is configured as a pressure turbine, the blades of the first turbine being configured to rotate the first turbine rotor in response to kinetic energy imparted by impingement of the exhaust pulses against the blades, the first turbine having a pressure ratio smaller than that of the second turbine.

6. The compound cycle engine as defined in claim 5, wherein each rotary unit is a Wankel engine.
7. The compound cycle engine as defined in claim 6, wherein each Wankel engine has a volumetric compression ratio within a range defined from 6:1 to 8:1.
8. The compound cycle engine as defined in claim 5, wherein the compound cycle engine includes at least two rotary units, the exhaust port of each housing being in fluid communication with a respective first turbine inlet, the first turbine inlets being circumferentially spaced apart.
9. The compound cycle engine as defined in claim 5, wherein the flowpath of the first turbine is an axial flowpath.
10. The compound cycle engine as defined in claim 5, wherein the compressor and the second turbine are in driving engagement through a turbocharger shaft rotatable independently of the common shaft.

11. The compound cycle engine as defined in claim 5, wherein the compressor and the second turbine are in driving engagement through a turbocharger shaft, and wherein the turbocharger shaft and the common shaft are drivingly interconnected.

12. The compound cycle engine as defined in claim 5, wherein the compressor and the second turbine are in driving engagement through a turbocharger shaft, and wherein the common shaft is an output shaft having a different axis than that of the turbocharger shaft, the compressor and the second turbine each including at least one radial impeller.

13. The compound cycle engine as defined in claim 5, wherein the common shaft is an output shaft connected to the rotor of each rotary unit, the first turbine being drivingly engaged to the output shaft through a transmission.

14. The compound cycle engine as defined in claim 5, further comprising common rail fuel injectors for each rotary unit, and a heavy fuel source in communication with the fuel injectors.

15. The compound cycle engine as defined in claim 5, wherein the first turbine has a pressure ratio of about 1.

16. A compound cycle engine comprising:

at least one rotary engine having a rotor sealingly and rotationally received within a respective housing having an inlet port and an exhaust port, the rotor of each rotary engine being drivingly engaged to a common shaft;

a first turbine in proximity of each rotary engine and having a first turbine rotor drivingly engaged to the common shaft;

a respective exhaust pipe providing fluid communication between each exhaust port and the first turbine, each exhaust pipe communicating with a flowpath of the first turbine at a location upstream of the first turbine rotor to circulate exhaust pulses from the exhaust port to the first turbine rotor;

a turbocharger including a compressor and a second turbine drivingly engaged to one another;

an inlet duct providing fluid communication between an outlet of the compressor and the inlet port of each rotary engine; and

a turbine pipe providing fluid communication between an outlet of the first turbine and an inlet of the second turbine;

wherein the first turbine is configured as a velocity turbine and the second turbine is configured as a pressure turbine, the first turbine rotor having blades extending across the flowpath and configured to rotate the first turbine rotor in response to kinetic energy imparted by impingement of the exhaust pulses against the blades, the first turbine having a pressure ratio smaller than that of the second turbine.

17. The compound cycle engine as defined in claim **16**, wherein the compound cycle engine includes at least two rotary engines, the respective exhaust pipe of each rotary engine being in fluid communication with a respective first turbine inlet, the first turbine inlets being circumferentially spaced apart.

18. The compound cycle engine as defined in claim **16**, wherein the compressor and the second turbine are drivingly engaged through a turbocharger shaft rotatable independently of the common shaft.

19. The compound cycle engine as defined in claim **16**, wherein the compressor and a second turbine are drivingly engaged through a turbocharger shaft, and wherein the turbocharger shaft and the common shaft are drivingly interconnected.

20. The compound cycle engine as defined in claim **16**, wherein the first turbine rotor is an axial rotor.

21. The compound cycle engine as defined in claim **16**, wherein each rotary engine is a Wankel engine.

22. The compound cycle engine as defined in claim **16**, further comprising common rail fuel injectors for each rotary engine, and a heavy fuel source in communication with the fuel injectors.

23. The compound cycle engine as defined in claim **16**, wherein the first turbine has a pressure ratio of about 1.
