ABSTRACT
One aspect of the present invention relates to the surprising discovery that modification of a glycan structure on a human SAP polypeptide can increase the biological activity of the SAP polypeptide relative to a corresponding sample of wild-type SAP isolated from human serum. The disclosure provides both variant human SAP polypeptides and methods for making the same. In particular, the present invention provides methods and compositions for in vitro and in vivo addition, deletion, or modification of sugar residues to produce SAP polypeptides, such as a human SAP polypeptide, having a desired glycosylation pattern.

SERUM AMYLOID P DERIVATIVES AND THEIR PREPARATION AND USE

CROSS-REFERENCE TO RELATED APPLICATIONS

[0001] This application claims the benefit of U.S. Provisional Application Ser. No. 61/217,931 filed on Jun. 4, 2009. All of the teachings of the above-referenced application are incorporated herein by reference.

SEQUENCE LISTING

[0002] The instant application contains a Sequence Listing which has been submitted via EFS-Web and is hereby incorporated by reference in its entirety. Said ASCII copy, created on Jun. 3, 2010, is named 1041120020.txt, and is 7,550 bytes in size.

BACKGROUND OF THE INVENTION

[0003] Serum Amyloid P(SAP) is a member of the pentraxin family of proteins. SAP is secreted by the liver and circulates in the blood as a stable pentamer. Previous research demonstrates SAP has an important role in both the initiation and resolution phases of the immune response. SAP can bind to sugar residues on the surface of bacteria and thereby promote their opsonization and engulfment by antigen-presenting cells. SAP also binds to free DNA and chromatin generated by apoptotic cells at the resolution of an immune response, thus preventing a secondary inflammatory response against these antigens. Molecules bound by SAP are removed from extracellular areas due to the ability of SAP to bind to all three classical Fcγ receptors (FcγR), having a particular affinity for FcγRII (CD12) and FcγRII (CD16). After receptor binding, SAP and any attached complex are generally internalized and processed by the cell.

[0004] Recently, it has been suggested that SAP can be used as a therapeutic agent to treat various disorders, including fibrosis-related disorders, hypersensitivity disorders, autoimmune disorders, mucositis, and inflammatory disorders such as those caused by microbial infections. See, for example, U.S. patent application Ser. Nos. 11/707,333, 12/217,617, 12/720, 845, and 12/720,847. Protein therapeutics for treating human diseases have revolutionized the health care industry. However, there are many difficulties in producing a protein therapeutic having the necessary potency and/or in sufficient quantity to be useful as a therapeutic agent. Many potential therapeutic agents are modified to increase their biological activity, such as plasma half-life, relative to the naturally-derived protein. Recombinant expression technology is usually implemented to produce polypeptides in sufficient quantity. Unfortunately, many recombinant systems produce polypeptides having different biological properties than the naturally-derived forms, which may affect the pharmacokinetics, safety, and efficacy of a therapeutic product.

[0005] Therefore, a need remains for developing SAP polypeptides, and methods of manufacturing them, suitable for therapeutic treatment of humans.

SUMMARY OF THE INVENTION

[0006] In part, the disclosure provides variant Serum Amyloid P(SAP) polypeptides and methods for producing them. The present invention includes methods and compositions for in vitro and in vivo addition, deletion, or modification of sugar residues to produce variant SAP polypeptides having a desired glycosylation pattern.
chain is substantially free of α-2,6-linked sialic acid moieties. Glycovariant SAP polypeptides of the invention may comprise one or more branches, e.g., the N-linked oligosaccharide chain may be characterized as having a bi-antennary, tri-antennary, tetra-antennary, or a penta-antennary structure. In some embodiments, the N-linked oligosaccharide chain comprises a pentasaccharide core of Manα(1,6)-(Manα(1,3)-Manβ(1,4)GlcNAcβ(1,4)GlcNAcβ(1,3)N-AcP. In some embodiments, the N-linked oligosaccharide chain comprises at least one branch having the structure NeuNAcβ2Manα6GlcNAcβ4GlcNAcβ2Manα6. In some embodiments, at least one branch of the N-linked oligosaccharide chain is substantially free of galactose and N-acetylglucosamine. In some embodiments, all the branches of the N-linked oligosaccharide chain are substantially free of galactose and N-acetylglucosamine. In some embodiments, at least one branch of the N-linked oligosaccharide chain comprises one or more mannose residues. In some embodiments, the N-linked oligosaccharide chain comprises at least one fucose residue. Any of the glycovariant SAP polypeptides of the invention may comprise at least one modified glycosyl residue. A modified glycosyl residue may be conjugated to one or more modifying groups selected from water-soluble and insoluble polymers, therapeutic moieties, diagnostic agents, and biomolecules.

In certain aspects, the SAP polypeptide of the invention may be a recombinant polypeptide. SAP polypeptide of the invention may comprise an amino acid sequence at least 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% identical to SEQ ID Nos. 1, 2, 3, or 4. Preferably, the SAP polypeptide is a human SAP protein. A human SAP polypeptide of the invention may comprise an amino acid sequence at least 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% identical to SEQ ID NO: 1.

In certain aspects, the human SAP polypeptide of the invention is a fusion protein comprising an SAP domain and one or more heterologous domains. The heterologous domain may enhance one or more of in vivo stability, in vivo half-life, uptake/administration, tissue localization or distribution, formation of protein complexes, and/or purification.

In certain aspects, the human SAP polypeptide of the invention comprises one or more modified amino acid residues, e.g., a PEGylated amino acid, a glycosylated (e.g., N-linked glycosylation) amino acid, a prenylated amino acid, an acetylated amino acid, a biotinylated amino acid, and/or an amino acid conjugated to an organic derivatizing agent. The modified amino acid residues may enhance one or more of in vivo stability, in vivo half-life, uptake/administration, tissue localization or distribution, formation of protein complexes, and/or purification.

In preferred embodiments, human SAP polypeptides of the invention have increased biological activity relative to a corresponding sample of wild-type SAP isolated from human serum. In certain aspects, the SAP polypeptides of the invention have an IC₅₀ for inhibiting the differentiation of monocytes into macrophages in vitro that is less than one-half, less than one-third, less than one-fourth, less than one-tenth, or less than one-hundredth of that of a corresponding sample of wild-type SAP isolated from human serum.

In certain aspects, methods of making any of the human SAP polypeptides of the invention comprise an additional step of enzymatically or chemically altering the SAP polypeptide to attach an N-linked or O-linked oligosaccharide chain to the SAP polypeptide or to modify the existing N-linked or O-linked oligosaccharide chain of the SAP polypeptide. In some embodiments, enzymatically or chemically altering the SAP polypeptide comprises treating the SAP polypeptide with one or more enzymatic proteins selected from glycosyltransferases, glycosidases, and phosphatas. In some embodiments, the process of enzymatically or chemically altering the SAP polypeptide is effected in the presence of one or more sugar precursors. Suitable sugar precursors include, but are not limited to, UDP-N-acetylglucosamine, CMP-N-glycolylneuraminic acid UDP-N-acetylneuraminic acid, CMP-N-acetylneuraminic acid, UDP-galactose, and GDP-fucose. In some embodiments, the process of enzymatically or chemically altering the SAP polypeptide removes one or more terminal α-2,6-linked sialic acid moieties from the N-linked or O-linked oligosaccharide chain. In some embodiments, the process of enzymatically or chemically altering the isolated SAP polypeptide replaces one or more terminal α-2,6-linked sialic acid moieties on the oligosaccharide chain with one or more α-2,3-linked sialic acid moieties.

The disclosure further provides pharmaceutical preparations of human SAP polypeptides of the invention suitable for use in a mammal. Pharmaceutical preparations of the invention include at least one of the SAP polypeptides disclosed herein and a pharmaceutically acceptable carrier. In some embodiments, the pharmaceutical preparation further comprises an additional active agent. In some embodiments, the pharmaceutical preparation is prepared as a sustained release formulation. In some embodiments, pharmaceutical preparations of the disclosure are suitable for administration to a patient topically, by injection, by intravenous injection, by inhalation, by continuous depot, or by pump.

The disclosure further provides methods for treating or preventing SAP-responsive disorders or conditions by administering to a patient in need thereof a therapeutically effective amount of one or more of the SAP polypeptides of the invention. SAP-responsive disorders or conditions include, but are not limited to, fibrotic or fibroproliferative disorders or conditions, hypersensitivity disorders or conditions, autoimmune disorders or conditions, inflammatory diseases or conditions, and mucositis. The SAP polypeptide of the invention may be administered to a patient topically, by injection, by intravenous injection, by inhalation, by continuous depot or pump, or a combination thereof. In some embodiments, the SAP polypeptide of the invention is administered with one or more additional active agents.

BRIEF DESCRIPTIONS OF THE DRAWINGS

FIG. 1. Fig. 1. Fibrocyte differentiation assay. An ELISA-based assay was used to measure production of MDC after incubation of monocytes with SAP polypeptides. The Y-axis indicates the average potency (i.e., average of 7 independent experiments) of human serum-derived SAP (hSAP) compared to recombinant human SAP (rShSAP) isolated from CHO-S cells. Relative activity of hSAP is set at 1.0.

FIG. 2. Glycan structural analysis of variant SAP polypeptides. Liquid Chromatography Mass Spectrometry (LCMS) analysis (A) and Anion-Exchange High Performance Liquid Chromatography (AEX-HPLC) analysis (B) was used to determine the sialic acid linkages on glycoremolded recombinant human SAP isolated from CHO—S cells. Liquid Chromatography Mass Spectrometry (LCMS) analysis (C) and Anion-Exchange High Performance Liquid Chromatography (AEX-HPLC) analysis (D) was used to deter-
mine the sialic acid linkages on glycoremodeled hSAP (human serum-derived SAP). Liquid Chromatography Mass Spectrometry (LCMS) analysis (E) and Anion-Exchange High Performance Liquid Chromatography (AEX-HPLC) analysis (F) was used to determine the sialic acid linkages on rhSAP that was treated with an α,2,3-sialyltransferase to increase the number of terminal 2,3-linked sialic acids on the SAP glycans. For LCMS figures, the X-axis represents mass in Daltons, and the Y-axis represents relative intensity. For the HPLC traces, the X-axis is the time in minutes, and the Y-axis is absorbance units (mAU).

**0027** FIG. 3. Fibrocyte differentiation assay. An ELISA-based assay was used to measure production of MDC after incubation of monocytes with SAP variant polypeptides. The Y-axis indicates the average relative activity of each SAP variant compared to a hSAP reference standard, for which the activity is set at 1.0 (see the left-most bar).

**0028** FIG. 4. Fibrocyte differentiation assay. Monocytes were treated with hMCSF and then subsequently quantified for fibrocyte differentiation. The X-axis represents the concentration of hMCSF incubated with donor monocytes. The Y-axis indicates the amount of fibrocyte proliferation at day five as measured by the enumeration of fibrocytes per 5.0x10^5 cells.

**0029** FIG. 5. Fibrocyte differentiation assay. Monocytes were treated with hSAP and then subsequently quantified for fibrocyte differentiation. The X-axis indicates the concentration of hSAP incubated with donor monocytes. The Y-axis indicates the amount of fibrocyte proliferation at day five as measured by the enumeration of fibrocytes per 5.0x10^5 cells.

**DETAILED DESCRIPTION OF THE INVENTION**

**Overview**

**0030** Most naturally occurring peptides have carbohydrate moieties (i.e., glycans) attached to the peptide via specific linkages to certain amino acids along the length of the primary peptide chain, thus forming "glycopeptides." The glycosylation pattern on any given peptide can have enormous implications for the function of that peptide. For example, the structure of the N-linked glycans on a peptide can impact various characteristics of the peptide, including protease susceptibility, intracellular trafficking, secretion, tissue targeting, biological half-life, and antigenicity. The alteration of one or more of these characteristics greatly affects the efficacy of a peptide in its natural setting.

**0031** The glycan structures found in naturally occurring glycopeptides are typically divided into two classes, N-linked and O-linked glycans. Peptides expressed in eukaryotic cells are typically N-glycosylated on asparagine residues at sites in the peptide primary structure containing the sequence asparagine-X-serine/threonine, where X can be any amino acid except proline and aspartic acid. The carbohydrate portion of such peptides is known as an N-linked glycan or N-linked oligosaccharide. The early events of N-glycosylation occur in the endoplasmic reticulum (ER) and are conserved in mammals, plants, insects and other higher eukaryotes. First, an oligosaccharide chain comprising fourteen sugar residues is constructed on a lipid carrier molecule. As the nascent peptide is translated and translocated into the ER, the entire oligosaccharide chain is transferred to the amide group of the asparagine residue in a reaction catalyzed by a membrane-bound glycosyltransferase enzyme. The N-linked glycan is further processed both in the ER and in the Golgi apparatus. The further processing generally entails removal of some of the sugar residues and addition of other sugar residues in reactions catalyzed by glycosylases and glycosyltransferases specific for the sugar residues removed and added.

**0032** Typically, the final structures of the N-linked glycans are dependent upon the organism in which the peptide is produced. For example, peptides produced in bacteria are generally unglycosylated. Peptides expressed in insect cells typically contain high mannose or paucimannose N-linked oligosaccharide chains. Peptides produced in mammalian cell culture are usually differentially glycosylated depending upon the species and cell culture conditions. Even in the same species and under the same conditions, a certain amount of heterogeneity in the glycosyl chain is sometimes encountered. In general, peptides produced in plant cells comprise glycan structures that differ significantly from those produced in animal cells.

**0033** A variety of methods have been proposed in the art to customize the glycosylation pattern of a peptide, including methods described in the Published International Applications Nos. WO 99/22764, WO 98/58964, and WO 99/54342 as well as in U.S. Pat. No. 5,047,335. Essentially, many of the enzymes required for the in vitro glycosylation of peptides have been cloned and sequenced. In some instances, these enzymes have been used in vitro to add specific sugars to a glycan on a peptide. In other instances, cells have been genetically engineered to express a combination of enzymes and desired peptides such that addition of a desired sugar moiety to an expressed peptide occurs within the cell.

**0034** Two principal classes of enzymes are used in the synthesis of carbohydrates: glycosyltransferases and glycosidases. Glycosyltransferases add or modify the existing oligosaccharide structures on a peptide. Glycosyltransferases are effective for producing specific products with good stereochemical and regiochemical control. Glycosyltransferases have been used to prepare oligosaccharides and to modify terminal N- and O-linked carbohydrate structures, particularly on peptides produced in mammalian cells. For example, the terminal oligosaccharides of glycopeptides can be completely sialylated and/or fucosylated to provide more consistent sugar structures using glycosyltransferases, which may improves glycopeptide pharmacodynamics and a variety of other biological properties.

**0035** The glycosidases are further classified as exoglycosidases (e.g., β-mannosidase, β-glucosidase), and endoglycosidases (e.g. Endo-A, Endo-M). Glycosidases normally catalyze the hydrolysis of a glycosidic bond. However, under appropriate conditions, they can be used to form this linkage. Most glycosidases used for carbohydrate synthesis are exoglycosidases; the glycosyl transfer occurs at the non-reducing terminus of the substrate. The glycosidase binds a glycosyl donor in a glycosyl-enzyme intermediate that is either intercepted by water to yield the hydrolysis product, or by an acceptor, to generate a new glycoside or oligosaccharide. An exemplary pathway using an exoglycosidase is the synthesis of the core triasaccharide of all N-linked glycopeptides, including the β-mannoside linkage, which is formed by the action of β-mannosidase (Singh et al., Chem. Commun. 993-994 (1996)). Although their use is less common than that of the exoglycosidases, endoglycosidases are also utilized to prepare carbohydrates. Endoglycosidases can be used to transfer an entire oligosaccharide chain, rather than a monosaccharide, onto a polypeptide. Oligosaccharide fragments have been added to substrates using endo-β-N-acetyl-
glucosamines, such as endo-F andendo-M (Wang et al., Tetrahedron Lett. 37: 1975-1978; and Haneda et al., Carbohydr. Res. 292: 61-70 (1996). Each of these classes of enzymes has been successfully used to produce glycosylated peptides. For a general review, see, Crout et al., Curr. Opin. Chem. Biol. 2: 98-111 (1998).

**[0036]** Serum amyloid P (SAP) is a naturally occurring serum protein in mammals composed of five identical subunits, or “subunits,” which are non-covalently associated in a disk-like complex. SAP belongs to the pentraxin super family of proteins, which are characterized by this cyclic pentameric structure. The classical short pentraxins include SAP as well as C-reactive protein (Osmand, A. P., et al., Proc. Nat. Acad. Sci., 74: 739-743, 1997). SAP is normally synthesized in the liver and has a physiological half-life of twenty-four hours. The sequence of the human SAP subunit is disclosed below, which corresponds to amino acids 20-223 of Gene bank Accession NO. NP_001630 (signal sequence not depicted).

-continued

** [0037] ** One aspect of the present invention relates to the surprising discovery that modification of a glycan structure on a human SAP polypeptide can increase the biological activity of the SAP polypeptide relative to a corresponding sample of wild-type SAP isolated from human serum. As demonstrated by the examples of the disclosure, isolated SAP from human serum contains only α-2,6-linked sialic acid residues. In contrast, recombinant human SAP produced in CHO cells contains only α-2,3-linked sialic acid residues. Using in vitro cell-based bioassays, α-2,3-linked sialic acid SAP polypeptides were demonstrated to have consistently higher activity than wild-type SAP (i.e., SAP comprising α-2,6-linked sialic acid moieties) isolated from human serum. The variant SAP polypeptides of the invention would be more effective as therapeutic agents due to their increased biological potency. For example, more potent SAP variants may require lower dosing and/or less frequent dosing relative to wild-type SAP isolated from human serum. The present disclosure provides both variant human SAP polypeptides and methods for making the same. In particular, the disclosure includes methods and compositions for in vitro and in vivo addition, deletion, or modification of sugar residues to produce a human SAP polypeptide having a desired glycosylation pattern.

**DEFINITIONS**

**[0038]** Unless defined otherwise, all technical and scientific terms used herein generally have the same meaning as commonly understood by one of ordinary skill in the art. Generally, the nomenclature used herein and the laboratory procedures in cell culture, molecular genetics, organic chemistry, and nucleic acid chemistry and hybridization are those well known and commonly employed in the art. Standard techniques are used for nucleic acid and peptide synthesis. The techniques and procedures are generally performed according to conventional methods in the art and various general references (e.g., Sambrook et al., 1989, Molecular Cloning: A Laboratory Manual, 2d ed. Cold Spring Harbor Laboratory Press, Cold Spring Harbor, N.Y.), which are provided throughout this document.

**[0039]** The articles “a” and “an” are used herein to refer to one or to more than one (i.e., at least one) of the grammatical object of the article. By way of example, “an element” means one element or more than one element.

**[0040]** As used herein, the terms “treatment” and “treating”, refer to obtaining a desired pharmacologic and/or physiologic effect. The effect may be prophylactic in terms of completely or partially preventing a disorder or symptom thereof and/or may be therapeutic in terms of a partial or complete cure for a disorder and/or adverse affect attributable to the disorder. “Treatment”, as used herein, covers any treatment of a disease in a mammal, particularly in a human, and includes: (a) increasing survival time; (b) decreasing the risk of death due to the disease; (c) inhibiting the disease, i.e., arresting its development or reducing the rate of disease progression; and (d) relieving the disease, i.e., causing regression of the disease.
As used herein, a therapeutic that “inhibits” or “prevents” a disorder or condition is a compound that, in a statistical sample, reduces the occurrence of the disorder or condition in the treated sample relative to an untreated control sample, or delays the onset or reduces the severity of one or more symptoms of the disorder or condition relative to the untreated control sample.

As used herein the terms “subject” and “patient” refer to animals including mammals, such as humans. The term “mammal” includes primates, domesticated animals including dogs, cats, sheep, cattle, horses, goats, pigs, mice, rats, rabbits, guinea pigs, captive animals such as zoo animals, and wild animals.

As used herein the term “tissue” refers to an organ or set of specialized cells such as skin tissue, lung tissue, kidney tissue, and other types of cells.

The term “therapeutic effect” is art-recognized and refers to a local or systemic effect in animals, particularly mammals, and more particularly humans caused by a pharmacologically active substance. The phrase “therapeutically effective amount” means that amount of such a substance that produces some desired local or systemic effect at a reasonable benefit/risk ratio applicable to any treatment. The therapeutically effective amount of such substance will vary depending upon the subject and disease condition being treated, the weight and age of the subject, the severity of the disease condition, the manner of administration, which can readily be determined by one of ordinary skill in the art. For example, certain compositions described herein may be administered in a sufficient amount to produce a desired effect at a reasonable benefit/risk ratio applicable to such treatment.

As used herein, the term “nucleic acid” refers to a polynucleotide such as deoxyribonucleic acid (DNA) and, where appropriate, ribonucleic acid (RNA). The term should also be understood to include, as equivalents, analogs of either RNA or DNA made from nucleotide analogs, and, as applicable to the embodiment being described, single-stranded (such as sense or antisense) and double-stranded polynucleotide.

The terms “peptides”, “proteins” and “polypeptides” are used interchangeably herein. The term “purified protein” refers to a preparation of a protein or proteins that are preferably isolated from, or otherwise substantially free of, other proteins normally associated with the protein(s) in a cell or cell lysate. The term “substantially free of other cellular proteins” or “substantially free of other contaminating proteins” is defined as encompassing individual preparations of each of the proteins comprising less than 20% (by dry weight) contaminating protein, and preferably comprises less than 5% contaminating protein. Functional forms of each of the proteins can be prepared as purified preparations by using a cloned gene as is well known in the art. By “purified”, it is meant that the indicated molecule is present in the substantial absence of other biological macromolecules, such as other proteins (particularly other proteins which may substantially mask, diminish, confuse or alter the characteristics of the component proteins either as purified preparations or in their function in the subject reconstituted mixture). The term “purified” as used herein preferably means at least 80% by dry weight, more preferably in the range of 85% by weight, more preferably 95-99% by weight, and most preferably at least 90.8% by weight, of biological macromolecules of the same type present (but water, buffers, and other small molecules, especially molecules having a molecular weight of less than 5000, can be present). The term “pure” as used herein preferably has the same numerical limits as “purified” immediately above.

“N-linked” oligosaccharides are those oligosaccharides that are linked to a peptide backbone through asparagine, by way of an asparagine-N-acetylglucosamine linkage. N-linked oligosaccharides are also called “N-glycans.” Naturally occurring N-linked oligosaccharides have a common pentasaccharide core of Man(α(1-6)-[Man(α(1-3)]-Man(β(1-4)-GlcNAc(β(1-4)-GlcNAc(β(1-N). They differ in the presence of, and in the number of branches (also called antennae) of peripheral sugars such as N-acetylglucosamine, galactose, N-acetylgalactosamine, fucose, and sialic acid. Optionally, this structure may also contain a core fucose molecule and/or a xylose molecule.

The term “sialic acid” refers to any member of a family of nine-carbon carboxylated sugars. The most common member of the sialic acid family is N-acetyl-neuraminic acid (often abbreviated as Neu5Ac, NeuAc, or NANA). A second member of the family is N-glycolyl-neuraminic acid (Neu5Gc or NeuGc), in which the N-acetyl group of Neu5Ac is hydroxylated. A third sialic acid family member is 2-keto-3-deoxy-norlanosonic acid (KDN) (Nanodo et al. (1986) J. Biol. Chem. 261: 11550-11557; Kanamori et al., J. Biol. Chem. 265: 21811-21819 (1990)). Also included are 9-substituted sialic acids such as a 9-O—C,3-acetyl-Neu5Ac like 9-O-laetly-Neu5Ac or 9-O-acetly-Neu5Ac, 9-deoxy-9-fluoro-Neu5Ac and 9-azido-9-deoxy Neu5Ac. For review of the sialic acid family, see, e.g., Varki, Glycobiology 2: 25-40 (1992); Sialic Acids: Chemistry, Metabolism and Function, R. Schauer, Ed. (Springer-Verlag, New York (1992)).

A “genetically engineered” or “recombinant” cell is a cell having one or more modifications to the genetic material of the cell. Such modifications include, but are not limited to, insertions of genetic material, deletions of genetic material and insertion of genetic material that is extrachromosomal whether such material is stably maintained or not.

As used herein, the term “modified sugar,” refers to a naturally- or non-naturally-occurring carbohydrate that is enzymatically added onto an amino acid or a glycosyl residue of a peptide in a process of the invention. The modified sugar is selected from a number of enzyme substrates including, but not limited to, sugar nucleotides (mono-, di-, and tri-phosphates), activated sugars (e.g., glycosyl halides, glycosyl mesylates) and sugars that are neither activated nor nucleotides. A “modified sugar” may be covalently functionalized with a “modifying group.” Useful modifying groups include, but are not limited to, water-soluble and -insoluble polymers, therapeutic moieties, diagnostic moieties, biomolecules. The locus of functionalization with the modifying group is selected such that it does not prevent the “modified sugar” from being added enzymatically to a peptide or glycosyl residue of the peptide.

Variant SAP Polypeptides

In part, the disclosure provides variant Serum Amyloid P (SAP) polypeptides. In particular, SAP variants of the invention include glycosylated human SAP polypeptides that comprise one or more N-linked or O-linked oligosaccharide chains each independently having one, two, three, four, five or more branches terminating with an α-2,3-linked sialic acid moiety. In some embodiments, all the branches of the N-linked or O-linked oligosaccharide chains terminate in α-2,3-linked moieties. Other SAP variants of the invention
include glycosylated human SAP polypeptides that contain an N-linked or O-linked oligosaccharide chains having at least 20%, 25%, 30%, 35%, 40%, 45%, 50%, 55%, 60%, 65%, 75%, 80%, 85%, or even at least 95% fewer α-2,6-linked sialic acid moieties than a wild-type SAP polypeptide derived from human serum. In some embodiments, the N-linked or O-linked oligosaccharide chains are substantially free of α-2, 6-linked sialic acid moieties, e.g., having less than 80%, 85%, 90%, 95%, 97%, 98% or even less than 99% α-2,6-linked sialic acid moieties relative to a wild-type SAP polypeptide derived from human serum). Glycovanent SAP polypeptides of the invention may comprise an N-linked oligosaccharide or O-linked chain having one or more branches (e.g., having a bi-antennary, tri-antennary, tetra-antennary, penta-antennary, etc. structure). In certain embodiments, SAP polypeptides of the invention comprise an N-linked or O-linked oligosaccharide chain wherein one, two, three, four, or five branches of the oligosaccharide chain are substantially free of galactose and N-acetylgalactosamine (e.g., having less than 80%, 85%, 90%, 95%, 97%, 98% or even less than 99% N-acetylgalactosamine relative to a wild-type SAP polypeptide derived from human serum). Certain SAP polypeptides of the invention have N-linked or O-linked oligosaccharide chains that are substantially free of galactose and N-acetylgalactosamine (e.g., having less than 80%, 85%, 90%, 95%, 97%, 98% or even less than 99% galactose and/or N-acetylgalactosamine relative to a wild-type SAP polypeptide derived from human serum). In some embodiments, SAP polypeptides of the invention comprise an N-linked or O-linked oligosaccharide chain wherein one, two, three, four, or five branches of the oligosaccharide chain contain one or more mannose residues. In certain embodiments, the SAP polypeptide of the invention comprises an N-linked oligosaccharide having a pentasaccharide core of Man(α-1,6)-(Man(α-1,3))-Man(β1,4)-GlcNAc(β1,4)-GlcNAc(β1,6)-Asn. This pentasaccharide core also may comprise one or more fucose or xylose residues. In certain embodiments, SAP polypeptides of the invention comprise an N-linked oligosaccharide chain wherein one, two, three, four, or five branches of the oligosaccharide chain have the structure NeuNAc2x3Galβ4GlcNAcβ2Manα6. SAP polypeptides of the invention also may comprise an N-linked oligosaccharide chain wherein all branches have the structure NeuNAc2x3Galβ4GlcNAcβ2Manα6.

**0052** Variant SAP polypeptides of the invention may comprise one or more “modified” sugar residues. Modified sugars are substituted at any position that allows for the attachment of the modifying moiety or group. In preferred aspects, modified sugar is substituted at a position that still allows the sugar to function as a substrate for an enzyme used to couple the modified sugar to the SAP peptide. A modifying group can be attached to a sugar moiety by enzymatic means, chemical means or a combination thereof, thereby producing a modified sugar, e.g., modified galactose, fucose, or sialic acid. Modifying groups suitable for use in the present invention as well as methods for conjugating these modifying groups to sugar residues are described in the following section.

**0053** In preferred aspects, variant SAP polypeptides of the invention have an IC₅₀ for inhibiting the differentiation of monocytes into fibrocytes in vitro that is less than 1/2, less than 1/4, less than 1/10, or less than 1/100 that of a corresponding sample of wild-type SAP isolated from human serum. In some embodiments, variant SAP polypeptides of the invention have an IC₅₀ for inhibiting the differentiation of monocytes into fibrocytes in vitro that is less than 1/2, less than 1/4, less than 1/10, or less than 1/100 that of a corresponding sample of wild-type SAP isolated from human serum.

**0054** Variant SAP polypeptides of the invention may have an IC₅₀ for inhibiting the differentiation of monocytes into fibrocytes in vitro that is less than 1/2, less than 1/4, less than 1/10, or less than 1/100 that of a corresponding sample of wild-type SAP isolated from human serum.

**0055** The term “SAP polypeptide” encompasses functional fragments and fusion proteins comprising any of the preceding. Generally, an SAP polypeptide will be designed to be soluble in aqueous solutions at biologically relevant temperatures, pH levels and osmolality. The SAP proteases that non-covalently associate together to form a tetrameric SAP complex may have identical amino acid sequences and/or post-translational modifications or, alternatively, individual SAP proteases within a single complex may have different sequences and/or modifications. The term SAP polypeptide includes polypeptides comprising any naturally occurring SAP polypeptide as well as any variant thereof (including mutants, fragments, and fusions). A SAP polypeptide of the invention may be a recombinant polypeptide. In preferred embodiments, the SAP polypeptide of the invention is a human SAP polypeptide.

**0056** In some embodiments, pharmaceutical compositions are provided comprising a variant SAP polypeptide of the invention, or a functional fragment thereof. In some aspects, the amino acid sequence of a SAP variant may differ from SEQ ID NO: 1 by one or more conservative or non-conservative substitutions. As used herein, “conservative substitutions” are residues that are physically or functionally similar to the corresponding reference residues, i.e., a conservative substitution and its reference residue have similar size, shape, electric charge, and/or chemical properties (e.g., the ability to form covalent or hydrogen bonds). Preferred conservative substitutions are those fulfilling the criteria defined for an accepted point mutation in Dayhoff et al., Atlas of Protein Sequence and Structure 5:345-352 (1978 & Supp). Examples of conservative substitutions are substitutions within the following groups: (a) valine, glycine; (b) glycine, alanine; (c) valine, isoleucine, leucine; (d) aspartic acid, glutamic acid; (e) asparagine, glutamine; (f) serine, threonine; (g) lysine, arginine, methionine; and (h) phenylalanine, tyrosine. Additional guidance concerning which amino acid changes are likely to be phenotypically silent can be found in Bowie et al., Science 247:1306-1310 (1990).

**0057** Variant SAP polypeptides and fragments thereof that retain biological function are useful in the pharmaceutical compositions and methods described herein. In some embodiments, a variant SAP polypeptide or fragment thereof binds FcγRI, FcγRIIA, and/or FcγRIIB. In some embodiments, a variant SAP polypeptide or fragment thereof inhibits one more of fibrocyte, fibrocyte precursor, myofibroblast precursor, and/or hematopoietic monocyte precursor differentiation. SAP variants may be generated by modifying the structure of an SAP polypeptide for such purposes as enhance-
ing therapeutic efficacy or stability (e.g., ex vivo shelf life and resistance to proteolytic degradation in vivo).

In certain aspects, the variant SAP polypeptides of the disclosure may further comprise post-translational modifications in addition to any that are naturally present in the SAP polypeptide. Such modifications include, but are not limited to, acetylation, carboxylation, glycosylation (e.g., O-linked oligosaccharides, N-linked oligosaccharides, etc.), phosphorylation, and lipidation. As a result, the modified SAP polypeptide may contain non-amino acid elements, such as polyethylene glycols, lipids, poly- or mono-saccharides, and phosphates.

In certain aspects, one or more modifications to the SAP polypeptide described herein may enhance the stability of the SAP polypeptide. For example, such modifications may enhance the in vivo half-life of the SAP polypeptide or reduce proteolytic degradation of the SAP polypeptide.

In certain aspects, variant SAP polypeptides of the invention include fusion proteins having at least a portion of the human SAP polypeptide and one or more fusion domains or heterologous portions. Well known examples of such fusion domains include, but are not limited to, polyhistidine, Glu-Glu, glutathione S-transferase (GST), thioredoxin, protein A, protein G, and immunoglobulin heavy chain constant region (Fc), maltose binding protein (MBP), or human serum albumin A fusion domain may be selected so as to confer a desired property. For example, some fusion domains are particularly useful for isolation of the fusion proteins by affinity chromatography. For the purpose of affinity purification, relevant matrices for affinity chromatography, such as glutathione-, amylose-, and nickel-, or cobalt-conjugated resins are used. As another example, a fusion domain may be selected so as to facilitate detection of the SAP polypeptides. Examples of such detection domains include the various fluorescent protein (e.g., GFP) as well as “epitope tags,” which are usually short peptide sequences for which a specific antibody is available. Well known epitope tags for which specific monoclonal antibodies are readily available include FLAG, influenza virus hemagglutinin (HA) and c-myc tags. In some cases, the fusion domains have a protease cleavage site that allows the relevant protease to partially digest the fusion proteins and thereby liberate the recombinant protein thereof. The liberated proteins can then be isolated from the fusion domain by subsequent chromatographic separation. In some cases, the SAP polypeptide may be fused to a heterologous domain that stabilizes the SAP polypeptide in vivo. By “stabilizing” is meant anything that increases serum half-life, regardless of whether this is because of decreased destruction, decreased clearance by the kidney, or other pharmacokinetic effect. Fusions with the Fc portion of an immunoglobulin and serum albumin are known to confer increased stability.

It is understood that different elements of the fusion proteins may be arranged in any manner that is consistent with the desired functionality. For example, an SAP polypeptide may be placed C-terminal to a heterologous domain, or, alternatively, a heterologous domain may be placed C-terminal to an SAP polypeptide. The SAP polypeptide and the heterologous domain need not be adjacent in a fusion protein, and additional domains or amino acid sequences (e.g., linker sequences) may be included C- or N-terminal to either domain or between the domains.

Methods of Producing Altered N-Glycosylation Molecules

Described herein are methods of producing variant human SAP polypeptides. The methods generally involve a step of contacting an SAP polypeptide with one or more chemical or enzymatic agents to produce or modify a glycosylation structure on the SAP polypeptide. The methods can be cell-based or non-cell based.

Enzymes useful for producing or modifying glycan structures are well known in the art. Most enzymes/proteins useful in the methods of the disclosure can be categorized into one of two functional classes: glycosyltransferases and glycosidases. Glycosyltransferases (e.g., N-acetylglucosaminyltransferases, galactosyltransferases, fucosyltransferases, sialyltransferases, glucosyltransferases, mannosyltransferases, etc.), as used herein, refers to any enzyme/protein that has the ability to transfer a donor sugar to an acceptor moiety. Glycosidases (e.g., glucosidases, mannosidases, N-acetylgalactosaminidases, sialidases, fucosidases, etc.), as used herein, refers to any enzyme/protein that has the ability to catalyze the hydrolysis of the glycosidic linkage between sugar moieties.

Cell-based methods for producing altered glycoforms of an SAP polypeptide use either wild-type (e.g., CHO cells) or genetically engineered cells that have at least one modified glycosylation activity relative to a human cell. Cells suitable for the methods of the disclosure include, for example, fungal cells, prokaryotic cell (i.e., bacteria, Archaea) plant cells, or animal cells (e.g., nematode, insect, plant, bird, reptile, or mammal (e.g., a mouse, rat, rabbit, hamster, gerbil, dog, cat, goat, pig, cow, horse, whale, monkey, or human)). The cells can be primary cells, immortalized cells, or transformed cells. Such cells can be obtained from a variety of commercial sources and research resource facilities, e.g., the American Type Culture Collection (Rockville, Md.). In certain aspects, the cell used for producing a variant SAP polypeptide is a CHO cell.

The term “glycosylation activity” refers to any activity that is (i) capable of adding N-linked or O-linked glycans to a target molecule (i.e., an oligosacchararyltransferase activity); (ii) removing N-linked or O-linked glycans from a target molecule; (iii) modifying one or more N-linked or O-linked glycans on a target molecule; (iv) modifying dolichol-linked oligosaccharides; (v) capable of aiding the activity of one or more of the activities under i-v. Accordingly, glycosylation activity includes, for example, glycosidase activity, glycosyltransferase activity, sugar nucleotide synthesis, modification, or transporter activity. Modification of one or more N-linked or O-linked glycans on a target molecule includes the action of a mannosylphosphoryltransferase activity, a kinase activity, or a phosphatase activity, e.g., a mannosylphosphoryltransferase, a kinase, or a phosphatase activity that alters the phosphorylation state of glycans on target molecules.

Engineered cells useful in the methods of the disclosure may have one or more genetic modifications including, but not limited to: (i) deletion of an endogenous gene encoding a protein having glycosylation activity; (ii) introduction of a recombinant nucleic acid encoding a mutant form of a protein (e.g., endogenous or exogenous protein) having a glycosylation activity; (iii) introduction or expression of an RNA molecule that interferes with the functional expression of a protein having the glycosylation activity; (iv) introduction of a recombinant nucleic acid encoding a wild-type (e.g., endogenous or exogenous) protein having glycosylation activity; or (v) altering the promoter or enhancer elements of one or more endogenous genes encoding proteins having glycosylation activity to thus alter the expression of
the encoded proteins. RNA molecules described above include, for example, small-interfering RNA (siRNA), short hairpin RNA (shRNA), anti-sense RNA, or micro RNA (miRNA). It is understood that item (ii) includes, for example, replacement of an endogenous gene (e.g., by homologous recombination) with a gene encoding a protein having greater glycosylation activity relative to the endogenous gene so replaced.

The genetically engineered cells described herein have one or more altered glycosylation activities such as: (i) an increase in one or more glycosylation activities in the genetically modified cell, (ii) a decrease in one or more glycosylation activities in the genetically modified cell, (iii) a change in the localization or intracellular distribution of one or more glycosylation activities in the genetically modified cell, or (iv) a change in the ratio of one or more glycosylation activities in the genetically modified cell relative to an unmodified cell of the same origin. It is understood that an increase in the amount of glycosylation activity can be due to overexpression of one or more proteins having glycosylation activity, an increase in copy number of an endogenous gene (e.g., gene duplication), or an alteration in the promoter, enhancer, or suppressor of an endogenous gene that stimulates an increase in expression of the protein encoded by the gene. A decrease in one or more glycosylation activities can be due to overexpression of a mutant form (e.g., a dominant negative form) of one or more proteins having glycosylation-altering activities, introduction or expression of one or more interfering RNA molecules that reduce the expression of one or more proteins having a glycosylation activity, or deletion of one or more endogenous genes that encode a protein having glycosylation activity.

Genetically engineered cells used by the methods of the disclosure can express (e.g., overexpress) wild-type or mutant genes encoding proteins having glycosylation activity. Such genes include, but are not limited to, ALG7, ALG13, ALG14, ALG1, ALG2, ALG11, RFT1, ALG3, ALG9, ALG12, ALG6, ALG8, ANL1, ALG10, ALG5, OST3, OST4, OST6, STT3, OST1, OST5, WBPI, SWP1, OST2, DPM1, SEC59, OCH1, MNM9, VAN1, MNM8, MNM10, MNM11, HOC1, MNM2, MNM5, MNM6, KTR1, YUR1, MNM4, KRE2, KTR2, KTR3, MNM1, MNM4, PNO1, MNM9, glucosidase I, glucosidase II, or endomannosidase. Genes encoding proteins having glycosylation activity can be from any species (e.g., lower eukaryotes (e.g., fungi, includ- ing yeasts) or trypanosomes), prokaryotes (i.e., bacteria or Archaen), plant, or animal (e.g., insect, bird, reptile, or mammal, such as mouse or rat, dog, cat, horse, goat, cow, pig, non-human primate, or human). It is understood that genetically engineered cells used for the methods of the disclosure can express any number of genes (e.g., genes encoding proteins having glycosylation activity) and/or any combination of one or more (e.g., 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 15, or 20 or more) of any of the genes recited herein. In addition, any genetically engineered cells used by the methods of the disclosure may comprise any number of mutations that alter or abrogate one or more glycosylation activities.

In some embodiments, the term “gene expression” or “expression” refers to the cellular processes by which a biologically active polypeptide is produced from a DNA sequence and exhibits a biological activity in a cell. As such, gene expression involves the processes of transcription and translation, but also involves post-transcriptional and post-translational processes that can influence a biological activity of a gene or gene product. These processes include, but are not limited to, RNA syntheses, processing, and transport, as well as polypeptide synthesis, transport, and post-translational modification of polypeptides.

For example, the disclosure provides methods for making an SAP polypeptide of the invention by expressing a SAP gene in a cell. In some embodiments, the cell may contain an endogenous SAP gene or fragment thereof. In other embodiments, a polynucleotide coding for an exogenous SAP polypeptide or fragment thereof may be introduced (e.g., transformed, transfected, etc.) into a cell. Suitable SAP polynucleotides that can be introduced into a cell include nucleic acid fragments as well as nucleic acid constructs or expression vectors. In preferred embodiments, the endogenous or exogenous gene encodes a human SAP polypeptide.

In some embodiments, the nucleic acid fragment, e.g., encoding a human SAP polypeptide, used to transform the host cell may include a Shine-Dalgarno site (e.g., a ribosome binding site) and a start site (e.g., the codon ATG) to initiate translation of the transcribed message to produce the enzyme. It may, also include a termination sequence to end translation. A termination sequence is typically a codon for which there exists no corresponding aminoacyl-tRNA, thus ending polypeptide synthesis. In some embodiments, a nucleic acid construct encoding an SAP polypeptide can be delivered, for example, as an expression plasmid that, when transcribed in the cell, produces as SAP polypeptide.

In some embodiments, a suitable expression vector comprises a nucleotide sequence encoding an SAP polypeptide of the invention operably linked to at least one regulatory sequence. Regulatory sequences are art-recognized and are selected to direct expression of any of the polypeptides of the disclosure. Accordingly, the term regulatory sequence includes promoters, enhancers and other expression control elements. Exemplary regulatory sequences are described in Goeddel; Gene Expression Technology: Methods in Enzymology, Academic Press, San Diego, Calif. (1990). For instance, any expression control sequence that regulates the expression of a DNA sequence when operatively linked to it may be used in these vectors to express any of the polypeptides of the disclosure. Such useful expression control sequences, include, for example, the early and late promoters of SV40, tet promoter, adenovirus or cytomegalovirus immediate early promoter, the lac system, the T7R system, the T7 promoter whose expression is directed by 17 RNA polymerase, the major operator and promoter regions of phage lambda, the control regions for fd coat protein, the promoter for 3-phosphoglycerate kinase or other glycylclic enzymes, the promoters of acid phosphatase, e.g., Pho5, the promoters of the yeast α-mating factors, the polyhedron promoter of the baculovirus system and other sequences known to control the expression of genes of prokaryotic or eukaryotic cells or their viruses, and various combinations thereof. It should be understood that the design of the expression vector may depend on such factors as the choice of the host cell to be transformed and/or the type of protein desired to be expressed. Moreover, the vector's copy number, the ability to control that copy number and the expression of any other protein encoded by the vector, such as antibiotic markers, should also be considered.

In some embodiments, the nucleic acid fragment or expression system used to transform the host cell optionally may include one or more marker sequences. Generally speak-
ing, suitable marker sequences typically encode a gene product, usually an enzyme that inactivates or otherwise detects or is detected by a compound in the growth medium. For example, the inclusion of a marker sequence may render the transformed cell resistant to an antibiotic, or it may confer compound-specific metabolism on the transformed cell. Examples of suitable marker sequences that confer resistance include kanamycin, ampicillin, chloramphenicol and tetracycline. Alternatively, rather than selective pressure, a marker gene may be used that allows for detection of particular colonies containing the gene, such as β-galactosidase, where a substrate is employed that provides for a colored product.

[0074] A variety of methods are suitable for transforming a cell of the present invention with a nucleic acid fragment or expression vector. Common transformation methods include electroporation, liposomal-mediated transformation, calcium-mediated transformation, and viral-mediated transfection.

[0075] In certain aspects, when a host cell is transformed with a nucleic acid fragment or expression system of the present invention, the gene (e.g., human SAP) in said system can be integrated into the chromosomal DNA of the host cells by a so-called homologous recombination and the expression system will be carried stably in the host.

[0076] In order to integrate the expression system in the vector into chromosomal DNA of the host cells, an appropriate selection marker gene may be used wherein said marker gene has a sequence homologous to the gene on chromosomal DNA of the specific host cell. Selection markers for such a purpose can be easily selected by a skilled person. As an example, a preferred marker is a gene that exists on a chromosome and relates to the metabolism of the host cells. Namely, it is preferred to use a host which has been modified in such a manner that the above-mentioned gene on the chromosome will be inactivated by an appropriate means such as a mutation. The host can then be subjected to a homologous recombination with an expression vector containing the corresponding intact gene, whereupon only transformants which contain the normal metabolism gene can grow to be selected. Therefore, if such a marker gene has been introduced to the expression vector, a homologous recombination will take place between the marker gene in said expression vector and the corresponding portion of the chromosomal DNA, whereby the expression cassette of the heterologous gene will simultaneously be integrated into the chromosomal DNA.

[0077] In some embodiments, the term “expressing” a protein in a cell also includes methods of introducing a protein itself into cells. Therefore, in certain aspects, the disclosure provides methods for making an SAP polypeptide of the invention by introducing an SAP polypeptide into a cell. Techniques for introducing polypeptides directly into a cell are known in the art and generally involve a process of cell membrane permeation. Such techniques include, but are not limited to, microinjection of SAP polypeptides; encapsulating an SAP polypeptide within membrane vesicles (e.g., liposomes, capsular bodies, erythrocyte ghosts, protoplasts, etc.) and contacting them with a cell membrane to thereby cause intracellular introduction of the SAP polypeptide by fusion; using physical methods (e.g., mechanical, chemical, electrical, etc.) that rely on macromolecules entering cells by diffusion through holes transiently introduced in their plasma membranes (e.g., scrape-loading, bead-loading, etc.); and by uptake through natural endocytosis owing to cellular phagocytosis. A method of intracellular introduction may utilize a receptor-mediated pathway, wherein one of various receptors expressed on the cell surface is set as a target and an SAP polypeptide is attached (covalently or non-covalently) to the cognate ligand that acts as a carrier moiety. Several methods have been described for introducing proteins into living cells using electrostatic adsorption, wherein the protein is first cationized and then contacted with the negatively charged surface of a cell (See Japanese Patent Publication No. 2004/049214).

[0078] In certain aspects, the disclosure provides CHO cells that express a SAP polypeptide. In some embodiments, the CHO cell expresses an exogenous SAP polypeptide. In preferred embodiments, the CHO cell expresses a human SAP polypeptide. In some embodiments, the disclosure provides CHO cells comprising a polynucleotide sequence encoding an SAP polypeptide. In preferred embodiments, the polynucleotide sequence encodes a human SAP polypeptide. Any of the aforementioned techniques may be used to “express” an SAP polypeptide of the invention in a CHO cell or any other suitable cell disclosed herein.

[0079] Where any of the glycosylation activities of the wild-type or genetically engineered cell are inducible or conditional on the presence of an inducing cue (e.g., a chemical or physical cue), the wild-type or genetically engineered cell can, optionally, be cultured in the presence of an inducing agent before, during, or subsequent to the introduction of the nucleic acid encoding a SAP polypeptide or a SAP polypeptide. For example, following introduction of the SAP polypeptide into the cell can be exposed to a chemical inducing agent that be capable of promoting the expression of one or more proteins having a wild-type or altered N-glycosylation activity. Where multiple inducing cues induce conditional expression of one or more proteins having wild-type and/or altered N-glycosylation activity, a cell can be contacted with multiple inducing agents. In some embodiments, the culture medium may be modified to produce the desired glycan structure on the SAP polypeptide. For example, the serum, glucose, and/or lipid (e.g., dolichol) concentration of the medium may be modified for optimal production of the desired SAP glycovariant. In some embodiments, the temperature, pH, and/or osmolarity of culture medium may be altered for optimal production of the desired SAP glycovariant.

[0080] A variant SAP polypeptide of the invention can be further processed in vivo or can be processed in vitro prior to or following isolation from the cell or cell medium. The further processing can include modification of one or more glycan residues of the SAP polypeptide or modification to the SAP polypeptide other than to its glycan structure(s). In some embodiments, the additional processing of the SAP polypeptide can include the addition (covalent or non-covalent joining) of one or more heterologous moieties. In some embodiments, the further processing involves enzymatic or chemical treatment of the SAP polypeptide. Enzymatic treatment can involve contacting the SAP polypeptide with one or more glycosidase, phosphodiesterase, phospholipase, glycosyltransferase, or protease for a time sufficient to induce the modification, addition, or deletion of glycan residues (e.g., galactose, mannose, fucose, sialic acid, xylose, N-acetylglucosamine, etc.) on the SAP polypeptide. Customization of an N-linked oligosaccharide chain may be accomplished by the sequential modification, addition, or deletion of the desired sugar moieties, using techniques well known in the art. Enzymatic cleavage of carbohydrate moieties on peptide variants
can be achieved by the use of a variety of endo- and exo-glycosidases as described by Thotakura et al., 1987, Meth. Enzymol. 138: 350. Exemplary methods of adding sugar moieties are disclosed in U.S. Pat. Nos. 5,876,980; 6,030,815, 5,728,554, and 5,922,577.

[0081] In certain embodiments, modification of the SAP glycan structure requires the presence of one or more sugar nucleotides. Exemplary sugar nucleotides that are used in the present invention include nucleotide mono-, di- or triphosphates or analogs thereof. In a preferred embodiment, the modified sugar nucleotide is selected from a UDP-glycoside, CMP-glycoside, or a GDP-glycoside. Even more preferably, the sugar nucleotide is selected from an UDP-galactose, UDP-galactosamine, UDP-glucose, UDP-glucosamine, GDP-mannose, GDP-fucose, CMP-sialic acid, CMP-N-glycolylneuraminic acid or CMP-NeuAc. In certain embodiments, a modified sugar nucleotide is utilized to add a modified sugar residue to the SAP polypeptide. N-acetyllactosamine derivatives of the sugar nucleotides are also of use in the method of the invention.

[0082] Chemical addition or removal of glycosyl moieties can be carried out by any suitable method. For example, chemical deglycosylation may involve exposure of the SAP polypeptide to trifluoromethanesulfonic acid, or another strong acid. This treatment results in the cleavage of most or all sugars except the linking sugar (N-acetylgalactosamine or N-acetylgalactosaminic), while leaving the peptide intact. Methods of chemical deglycosylation are described by Holdminder et al., 1987, Arch. Biochem. Biophys. 259: 52 and by Edge et al., 1981, Anal. Biochem. 118: 131. Chemical treatment can, for example, involve contacting the altered SAP polypeptide with an acid, such as hydrofluoric acid, for a time sufficient to induce modification of the SAP polypeptide. Hydrofluoric acid treatment, under certain conditions, specifically removes the mannose residues that are phosphodiester-linked to glycans, while leaving the phosphate on the glycan. An altered SAP polypeptide can be further processed by addition or removal of a phosphate group from one or more N-glycans. For example, an altered SAP polypeptide can be contacted with a mannosyl kinase or a mannosyl phosphatasae.

[0083] In certain aspects, it is desirable to modify only terminal sugar moieties on the SAP polypeptide glycan structure (N-linked or O-linked oligosaccharide). In some embodiments, one or more branches of the SAP glycan structure are modified by the addition, removal, substitution or modification of at least one terminal sialic acid residue. Suitable methods for modifying glycans described herein may be used to alter only the terminal sugar moiety on the SAP glycan structure. In some embodiments, a terminal sialic acid residue having an α-2,6-linkage, α-2,8-linkage, or α-2,9-linkage is replaced with one or more terminal α-2,3-linked sialic acid residue. In a particular aspect, human SAP comprising terminal α-2,6-linked sialic acid residues is modified according to one or more methods of the disclosure in order to replace one or more of the terminal α-2,6-linked sialic acid residues with one or more α-2,3-linked sialic acid residues. In some embodiments, a terminal α-2,3-linked sialic acid residue is modified to add one or more α-2,6-linked, α-2,8-linked, and/or α-2,9-linked sialic acid residues.

[0084] In certain aspects, the process of making an SAP polypeptide of the invention involves a first step of deglycosylating the SAP polypeptide. The SAP polypeptide may be partially or fully deglycosylated. In some embodiments, the first step of deglycosylation involves removing only terminal sugar moieties from at least one branch of the glycan structure on the SAP polypeptide. In some embodiments, the first step of deglycosylation removes at least one α-2,6-linked sialic acid residue. In some embodiments, the first step of deglycosylation removes at least one O-linked glycan. In some embodiments, the first step of deglycosylation removes all O-linked and N-linked glycans. In some embodiments, a deglycosylated SAP polypeptide (partially or fully) is further processed according to the methods of the disclosure, which includes but is not limited to, enzymatically or chemically modifying the partially or fully deglycosylated SAP polypeptide, introducing the partially or fully deglycosylated SAP polypeptide into a cell, or combination thereof, wherein the method(s) produce a variant SAP polypeptide of the invention. In some embodiments, after a partially or fully deglycosylated SAP polypeptide has been introduced into a cell, it may be further modified, in vivo or in vitro, according to the methods of the disclosure to produce a variant SAP polypeptide of the invention. Similarly, a partial or fully deglycosylated SAP polypeptide that is modified in vitro, using enzymatic or chemical methods described herein, may be introduced into a cell to produce a variant SAP polypeptide of the invention.

[0085] It is understood that an SAP polypeptide of the invention can be, but need not be, processed in a cell. For example, the disclosure also provides cell-free methods of producing a variant SAP polypeptide of the invention. In some aspects the cell-free methods include the step of contacting an SAP polypeptide, under glycosylation conditions, with a cell lysate prepared from a wild-type cell (e.g., a fungal cell, a plant cell, or an animal cell) or genetically engineered cell having at least one modified glycosylation activity, wherein contacting the SAP polypeptide with the cell lysate attaches an N-linked or O-linked oligosaccharide to the SAP polypeptide or modifies an existing N-linked or O-linked oligosaccharide on the SAP polypeptide. By “N-glycosylation conditions” is meant that a mixture (e.g., of SAP polypeptide and cell lysate) is incubated under conditions that allow for the desired altered N-glycosylation.

[0086] Suitable methods for obtaining cell lysates that preserve the activity or integrity of one or more glycosylation activities in the lysate can include the use of appropriate buffers and/or inhibitors, including nuclease, protease and phosphatase inhibitors that preserve or minimize changes in N-glycosylation activities in the cell lysate. Such inhibitors include, for example, chelators such as ethylenediaminetetraacetic acid (EDTA), ethylene glycol bis(β-aminoethyl ether) N,N,N,N-tetraacetic acid (EGTA), protease inhibitors such as phenylmethylsulfonyl fluoride (PMSF), apro tinin, leupeptin, antipain, and phosphatase inhibitors such as phosphatase, sodium fluoride, and vanadate. Inhibitors can be chosen such that they do not interfere with or only minimally adversely affect the N-glycosylation activity, or activities, of interest. Appropriate buffers and conditions for obtaining lysates containing enzymatic activities are described in, e.g., Ausubel et al. Current Protocols in Molecular Biology (Supplement 47), John Wiley & Sons, New York (1999); Harlow and Lane, Antibodies: A Laboratory Manual Cold Spring Harbor Laboratory Press (1988); Harlow and Lane, Using Antibodies: A Laboratory Manual, Cold Spring Harbor Press (1999); Tietz Textbook of Clinical Chemistry, 3rd ed. Burtis and Ashwood, eds. W.B. Saunders, Philadelphia, (1999).
A cell lysate can be further processed to eliminate or minimize the presence of interfering substances, as appropriate. If desired, a cell lysate can be fractionated by any of a variety of methods well known to those skilled in the art, including subcellular fractionation, and chromatographic techniques such as ion exchange, hydrophobic and reverse phase, size exclusion, affinity, and hydrophobic charge-induction chromatography (see, e.g., Scopes, Protein Purification: Principles and Practice, third edition, Springer-Verlag, New York (1993); Burton and Harding, J. Chromatogr. A 814:71-81 (1998)), or any other suitable purification technique.

A cell lysate can be prepared in which whole cellular organelles remain intact and/or functional. For example, a lysate can contain one or more of intact rough endoplasmic reticulum, intact smooth endoplasmic reticulum, or intact Golgi apparatus. Suitable methods for preparing lysates containing intact cellular organelles and testing for the functionality of the organelles are described in, e.g., Moreau et al. (1991) J. Biol. Chem. 266(7):4329-4333; Moreau et al. (1991) J. Biol. Chem. 266(7):4322-4328; Rexach et al. (1991) J. Cell Biol. 114(2):219-229; and Paulik et al. (1999) Arch. Biochem. Biophy. 367(2):265-273; the disclosures of each of which are incorporated herein by reference in their entirety.

The SAP polypeptide can be contacted with just one purified protein having glycosylation activity. In some embodiments, the SAP polypeptide can be contacted with more than one purified proteins having glycosylation activity. One or more proteins having glycosylation activity can be purified using standard protein isolation techniques. An SAP polypeptide can be contacted with one or more proteins in a suitable buffer for a time sufficient to induce modification of the SAP polypeptides as described above. The SAP polypeptide can be contacted with more than one protein at the same time or sequentially. Where the SAP polypeptide is contacted sequentially to more than one protein having glycosylation activity, the SAP polypeptide can, but need not, be purified after one or more steps. That is, an SAP polypeptide can be contacted with protein activity “A” and then purified before contacting the molecule to protein activity “B.” Methods of modifying peptides as such are known in the art, e.g., Lee and Park (2002) 30(6):716-720 and Fujita and Takegawa (2001) Biochem. Biophys. Res. Commun. 282(3):678-682, the disclosures of which are incorporated herein by reference in their entirety.

In certain aspects, the methods of the disclosure comprise a step of isolating an SAP polypeptide, e.g., from a cell or from components of a cell lysate. Many standard techniques for protein isolation are known in the art. For example, methods of isolating polypeptides include, but are not limited to, size-exclusion chromatography, reverse-phase chromatography, liquid chromatography (e.g., HPLC), affinity chromatography (e.g., metal chelation or immunoaffinity chromatography), ion-exchange chromatography, hydrophobic-interaction chromatography, precipitation, differential solubilization, immuno precipitation, centrifugation (e.g., ultracentrifugation, sucrose gradient centrifugation, etc.) or any combination thereof. In some embodiments, the SAP polypeptide may be conjugated to an affinity tag to facilitate purification of the polypeptide. Suitable affinity tags for SAP purification include, but are not limited to, chitin binding protein (CBP), maltose binding protein (MBP), glutathione-S-transferase (GST), streptavidin, biotin, and poly(His) tags. Affinity tags may be produced as part of the recombinant protein (i.e., as a fusion protein comprising a heterologous affinity tag domain and an SAP polypeptide domain) or attached (covalently or non-covalently) in vivo or in vitro to the SAP polypeptide. In some embodiments, multiple steps of purification may be used to isolate an SAP polypeptide. For example, an SAP polypeptide comprising a purification tag may be affinity-purified from a cell lysate or multi-component mixture using affinity purification. Then the affinity-purified SAP polypeptide may be further purified to remove any minor unwanted contaminants by an additional purification step, e.g., size exclusion chromatography or RP-HPLC. Where a polypeptide of the invention is produced in a cell, the SAP polypeptide can be isolated from the cell itself or from the media in which the cell was cultured. In some embodiments, SAP polypeptides of the invention are produced and secreted from a cell into the culture media. In these embodiments, isolation may comprise separation of the cellular fraction from the soluble, SAP-containing fraction (e.g., by centrifugation).

In some aspects, it can be advantageous to link the SAP polypeptide to a solid-phase support prior to contacting the target molecule with one or more N-glycosylation activities. Such linkage can allow for easier purification following the N-glycosylation modifications. Suitable solid-phase supports include, but are not limited to, multi-well assay plates, particles (e.g., magnetic or encoded particles), a chromatography column, or a membrane.

In some embodiments, any of the altered SAP polypeptides described herein can be attached to a heterologous moiety using enzymatic or chemical means. A “heterologous moiety” refers to any constituent that is joined (e.g., covalently or non-covalently) to the altered target molecule, which constituent is different from a constituent originally present on the SAP polypeptide. Heterologous moieties include, for example, water-soluble and -insoluble polymers, targeting moieties, therapeutic moieties, diagnostic moieties, and biomolecules.

SAP polypeptides of the invention may comprise one or more “modified” sugar residues. A modifying group can be attached to a sugar moiety by enzymatic means, chemical means or a combination thereof, thereby producing a modified sugar, e.g., modified galactose, fucose, or sialic acid. When a modified sialic acid is used, either a sialyltransferase or a trans-sialidase can be used in these methods. The sugars may be substituted at any position that allows for the attachment of the modifying moiety, yet which still allows the sugar to function as a substrate for the enzyme used to couple the modified sugar to the peptide.

In general, the sugar moiety and the modifying group of the inventive group is linked together through the use of reactive groups, which are typically transformed by the linking process into a new organic functional group or unreactive species. The sugar reactive functional group(s) may be attached at any position on the sugar moiety. Reactive groups and classes of reactions useful in practicing the present invention are generally those that are well known in the art of bioconjugate chemistry. Currently favored classes of reactions compatible with reactive sugar moieties are those which proceed under relatively mild conditions. These include, but are not limited to nucleophilic substitutions (e.g., reactions of amines and alcohols with acyl halides, active esters), electrophilic substitutions (e.g., enamine reactions) and additions to carbon-carbon and carbon-heteroatom multiple bonds (e.g., Michael reaction, Diels-Alder addition). These and other useful reactions are

Useful reactive functional groups pendent from a sugar nucleus or modifying group include, but are not limited to: (a) carboxyl groups and various derivatives thereof (e.g., N-hydroxysuccinimide esters, N-hydroxybenzotriazol esters, acid halides, aminomides, thioesters, p-nitrophenyl esters, alkyl, alkenyl, alkynyl and aromatic esters); (b) hydroxyl groups, which can be converted to, e.g., esters, ethers, aldehydes, etc.; (c) haloalkyl groups, wherein the haloide can be later displaced with a nucleophilic group such as, for example, an amine, a carboxylate anion, thiol anion, carbanion, or an alkoxide ion, thereby resulting in the covalent attachment of a new group to the functional group of the halogen atom; (d) dieneophile groups, which are capable of participating in Diels-Alder reactions such as, for example, maleimido groups (e) aldehyde or ketone groups, such that subsequent derivatization is possible via formation of carbonyl derivatives such as, for example, imines, hydrazones, semicarbazones or oximes, or via such mechanisms as Grignard addition or alkylithium addition; (f) sulfonamides; (g) thiols, which can be, for example, converted to disulfides or reacted with alkyl and acyl halides; (h) amine or sulfhydryl groups, which can be, for example, acylated, alkylated or oxidized; (i) alkenes, which can undergo, for example, cycloadditions, acylation, Michael addition, metathesis, Heck reaction, etc.; (j) epoxides, which can react with, for example, amines and hydroxyl compounds.

The reactive functional groups can be chosen such that they do not participate in, or interfere with, the reactions necessary to assemble the reactive sugar nucleus or modifying group. Alternatively, a reactive functional group can be protected from participating in the reaction by the presence of a protecting group. Those of skill in the art understand how to protect a particular functional group such that it does not interfere with a chosen set of reaction conditions. For examples of useful protecting groups, see, for example, Greene et al., Protective Groups in Organic Synthesis, John Wiley & Sons, New York, 1991.

In some embodiments, the modified sugar is an activated sugar. Activated modified sugars useful in the present invention are typically glycosides which have been synthetically altered to include an activated leaving group. As used herein, the term “activated leaving group” refers to those moieties which are easily displaced in enzyme-regulated nucleophilic substitution reactions. Many activated sugars are known in the art. See, for example, Vecdad et al., in Carbohydrate Chemistry and Biology, Vol. 2, Ernst et al. Ed., Wiley-VCH Verlag: Weinheim, Germany, 2000; Koduma et al., Tetrahedron Lett. 34: 6419 (1993); Loughed et al., J. Biol. Chem. 274: 37717 (1999)). Examples of such leaving groups include fluoro, chloro, bromo, tosylate, mesylate, triflate and the like. Preferred activated leaving groups for use in the present invention are those that do not significantly sterically encumber the enzymatic transfer of the glycoside to the acceptor. Accordingly, preferred embodiments of activated glycoside derivatives include glycosyl fluorides and glycosyl mesylates, with glycosyl fluorides being particularly preferred. Among the glycosyl fluorides, α-galactosyl fluoride, α-mannosyl fluoride, α-glucosyl fluoride, α-fucosyl fluoride, α-xyllosyl fluoride, α-sialyl fluoride, α-N-acetylglucosaminyl fluoride, α-N-acetylgalactosaminyl fluoride, β-galactosyl fluoride, β-mannosyl fluoride, β-glucosyl fluoride, β-fucosyl fluoride, β-xyllosyl fluoride, β-sialyl fluoride, β-N-acetylglucosaminyl fluoride and β-N-acetylgalactosaminyl fluoride are most preferred.

In certain aspects, a modified sugar residue is conjugated to one or more water-soluble polymers. Many water-soluble polymers are known to those of skill in the art and are useful in practicing the present invention. The term water-soluble polymer encompasses species such as saccharides (e.g., dextran, amylose, hyaluronic acid, poly(sialic acid), heparins, heparin sulfate, etc.); poly(amine acids); nucleic acids; synthetic polymers (e.g., poly(acrylic acid), poly(ethers), e.g., poly(ethylene glycol)); peptides, proteins, and the like. The present invention may be practiced with any water-soluble polymer with the sole limitation that the polymer must include a point at which the remainder of the conjugate can be attached.

In certain aspects, a modified sugar residue is conjugated to one or more water-insoluble polymers. In some embodiments, conjugation to a water-insoluble polymer can be used to deliver a therapeutic peptide in a controlled manner. Polymeric drug delivery systems are known in the art. See, for example, Dunn et al., Eds. Polymeric drugs and Drug Delivery Systems, ACS Symposium Series Vol. 469, American Chemical Society, Washington, D.C. 1991. Those of skill in the art will appreciate that substantially any known drug delivery system is applicable to the conjugates of the present invention.

Representative water-insoluble polymers include, but are not limited to, polyphosphazenes, poly(vinyl alcohols), polyamides, polycarbonates, polylakylene, polyacrylamides, polylakylene glycols, polyalkylene oxides, polyalkylene terephthalates, polyvinyl ethers, polyvinyl esters, polyvinyl halides, polyvinylpyrrolidone, polyglycolides, polysiloxanes, polystyrenes, poly(methyl methacrylate), poly(ethyl methacrylate), poly(butyl methacrylate), poly(isobutyln methacrylate), poly(hexyl methacrylate), poly(isodecyl methacrylate), poly(lauryl methacrylate), poly(phenyl methacrylate), poly(methyl acrylate), poly(isopropyl acrylate), poly(isobutyl acrylate), poly(octadecyl acrylate) polyethylene, polypropylene, poly(ethylene glycol), poly(ethylene oxide), poly(ethylene terephthalate), polyvinyl acetate, polylakylene chloride, polystyrene, polylakylene pyrrolidone, phthalonics, and polyvinylphenol, and copolymers thereof.
These and the other polymers discussed herein can be readily obtained from commercial sources such as Sigma Chemical Co. (St. Louis, Mo.), Polysciences (Warrenton, Pa.), Aldrich (Milwaukee, Wis.), Fluka (Ronkonkoma, N.Y.), and BioRad (Richmond, Calif.), or else synthesized from monomers obtained from these suppliers using standard techniques. Representative biodegradable polymers useful in the conjugates of the invention include, but are not limited to, polylactides, polyglycolides and copolymers thereof, poly(ethylene terephthalate), poly(butyric acid), poly(valeric acid), poly(lactide-co-caprolactone), poly[lactide-co-glycolide], polyanhydrides, polyorthoesters, blends and copolymers thereof. Of particular use are compositions that form gels, such as those including collagen, and pluronic.

In a preferred embodiment, one or more modified sugar residues are conjugated to one or more PEG molecules.

In certain aspects, the modified sugar is conjugated to a biomolecule. Biomolecule of the invention may include, but are not limited to, functional proteins, enzymes, antigens, antibodies, peptides, nucleic acids (e.g., single nucleotides or nucleosides, oligonucleotides, polynucleotides and single- and higher-stranded nucleic acids), lectins, receptors or a combination thereof. Some preferred biomolecules are essentially non-fluorescent, or emit such a minimal amount of fluorescence that they are inappropriate for use as a fluorescent marker in an assay. Other biomolecules may be fluorescent.

In some embodiments, the biomolecule is a targeting moiety. A “targeting moiety” and “targeting agent”, as used herein, refer to species that will selectively localize in a particular tissue or region of the body. In some embodiments, a biomolecule is selected to direct the SAP polypeptide of the invention to a specific intracellular compartment, thereby enhancing the delivery of the peptide to that intracellular compartment relative to the amount of underivatized peptide that is delivered to the tissue. The localization is mediated by specific recognition of molecular determinants, molecular size of the targeting agent or conjugate, ionic interactions, hydrophobic interactions and the like. Other mechanisms of targeting an agent to a particular tissue or region are known to those of skill in the art.

In some embodiments, the modified sugar includes a therapeutic moiety. Those of skill in the art will appreciate that there is overlap between the category of therapeutic moieties and biomolecules, i.e., many biomolecules have therapeutic properties or potential.

Classes of useful therapeutic moieties include, for example, non-steroidal anti-inflammatory drugs; steroidal anti-inflammatory drugs; adjuvants; antihistaminic drugs; antitussive drugs; antipruritic drugs; anticholinergic drugs; anti-emetic and antinauseant drugs; anorexics; central stimulant drugs; antiarrhythmic drugs; β-adrenergic blocker drugs; cardiotoxic drugs; antihypertensive drugs; diuretic drugs; vasodilator drugs; vasoconstrictor drugs; antilucre drugs; anesthetic drugs; antidepressant drugs; tranquilizer and sedative drugs; antipsychotic drugs; and antimicrobial drugs.

Other drug moieties useful in practicing the present invention include antineoplastic drugs, cytotoxic agents, antiestrogens, and antimetabolites. Also included within this class are radioisotope-based agents for both diagnosis (e.g., imaging and therapy), and conjugated toxins.

The therapeutic moiety can also be a hormone, a muscle relaxant, an antispasmodic, bone activating agent, endocrine modulating agent, modulator of diabetes, androgen, antiuretics, or calcitonin drug.

Other useful modifying groups include immunomodulating drugs, immunosuppressants, etc. Groups with anti-inflammatory activity, such as sulindac, etodolac, ketoprofen and ketorolac, are also of use. Other drugs of use in conjunction with the present invention will be apparent to those of skill in the art.

The altered N-glycosylation SAP polypeptides produced by the methods of the disclosure can be homogeneous (i.e., the sample of SAP polypeptide is uniform in specific N-glycan structure) or substantially homogeneous. By “substantially homogeneous” is meant that at least about 25% (e.g., at least about 27%, at least about 30%, at least about 35%, at least about 40%, at least about 45%, at least about 50%, at least about 55%, at least about 60%, at least about 65%, at least about 70%, at least about 75%, at least about 80%, at least about 85%, at least about 90%, or at least about 95%, or at least about 99%) of the SAP polypeptides contain the same specific N-glycan structure.

In some embodiments, variant SAP polypeptides of the invention have an IC50 for inhibiting the differentiation of monocytes into fibrocytes in vitro that is less than ½, less than ¼, less than ⅛, or less than ⅛₀₀ of that of a corresponding sample of wild-type SAP isolated from human serum. There are many well characterized methods for determining the responsiveness of Peripheral Blood Mononuclear Cells (PBMCs) or monocyte cells to SAP for fibrocyte differentiation. These methods may be used to determine the relative potency of any of the SAP variant polypeptides of the invention in comparison to a sample of human serum-derived SAP, any other SAP variant polypeptide, or other fibrocyte suppressant or activating agent. PBMCs or monocytes suitable for use in these methods may be obtained from various tissue culture lines. Alternatively, suitable cells for fibrocyte differentiation assays may be obtained from any biological sample that contains PBMC or monocyte cells. The biological sample may be obtained from serum, plasma, heathy tissue, or fibrotic tissue. In general, fibrocyte differentiation assays are conducted by incubating PBMC or monocyte cells in media with various concentrations of a SAP polypeptide to determine the degree of fibrocyte differentiation. The concentration of SAP can range from 0.0001 μg/mL to 1 μg/mL, and in some embodiments is 0.001 μg/mL, 1.0 μg/mL, 5 μg/mL, 10 μg/mL, 15 μg/mL, 20 μg/mL, 25 μg/mL, 30 μg/mL, 40 μg/mL, 45 μg/mL, 50 μg/mL, 100 μg/mL, 200 μg/mL, 300 μg/mL, or 500 μg/mL. In some assays, the media can be supplemented with at least 1-100 ng/mL hMCSF; the preferred concentration of hMCSF being 25 ng/mL. The indication that PBMC and monocytes have differentiated into fibrocytes can be determined by one skilled in the art. In general, fibrocytes are morphologically defined as adherent cells with an elongated spindle-shape and the presence of an oval nucleus. In some assays, cells are fixed and stained with Hema 3 before enumerating fibrocytes by direct counting, e.g., using an inverted microscope. The amount of fibrocyte differentiation is interpreted by one skilled in the art as an indication of a cell’s responsiveness to SAP. As indicated by the examples of the disclosure, a greater suppression of fibrocyte differentiation indicates a greater degree of SAP responsiveness. An alternative method of measuring fibrocyte differentiation involves determining the expression of fibrocyte-specific cell surface markers or secreted factors, e.g., cytokines (e.g., IL-1α, ENA-78/CXCL-5, PAI-1), fibronec-
tin, collagen-1. Methods of detecting and/or quantifying cell surface markers or secreted factors are well known in the art, including but not limited to various ELISA- and FACS-based techniques using immunoreactive antibodies against one or more fibrocyte specific markers. As described in the examples of the disclosure, measuring the expression of Macrophage Derived Chemokine (MDC) is an effective method of determining fibrocyte differentiation.

[0113] Methods for detecting and/or characterizing N-glycosylation (e.g., altered N-glycosylation) of a SAP polypeptide include DNA sequencer-assisted (DSA), fluorophore-assisted carbohydrate electrophoresis (FACE) or surface-enhanced laser desorption/ionization time-of-flight mass spectrometry (SELDI-TOF MS). For example, an analysis can utilize DSA-FACE in which, for example, glycoproteins are denatured followed by immobilization on, e.g., a membrane. The glycoproteins can then be reduced with a suitable reducing agent such as dithiothreitol (DATA) or β-mercaptoethanol. The sulfhydryl groups of the proteins can be carboxylated using an acid such as iodoacetic acid. Next, the N-glycans can be released from the protein using an enzyme such as N-glycosidase F. N-glycans, optionally, can be reconstituted and derivatized by reductive amination. The derivatized N-glycans can then be concentrated. Instrumentation suitable for N-glycan analysis includes, for example, the ABI PRISM® 377 DNA sequencer (Applied Biosystems). Data analysis can be performed using, for example, GENESCAN®. 3.1 software (Applied Biosystems). Optionally, isolated mannoproteins can be further treated with one or more enzymes to confirm their N-glycan status. Exemplary enzymes include, for example, α-mannosidase or α-1,2 mannosidase. Additional methods of N-glycan analysis include, for example, mass spectrometry (e.g., MALDI-TOF-MS), high-pressure liquid chromatography (HPLC) on normal phase, reversed phase and ion exchange chromatography (e.g., with pulsed amperometric detection when glycans are not labeled and with UV absorbance or fluorescence if glycans are appropriately labeled). See also Callewaert et al. (2001) Glycobiology 11(4):275-281 and Freire et al. (2006) Bioconj. Chem. 17(2):559-564, the disclosures of each of which are incorporated herein by reference in their entirety.

Treatment Methods

[0114] In one aspect, the disclosure provides methods for treating an SAP-responsive disorder in a patient by administering a therapeutically effective amount of a variant SAP polypeptide of the invention to a patient in need thereof. The dosage and frequency of treatment can be determined by one skilled in the art and will vary depending on the symptoms, age and body weight of the patient, and the nature and severity of the disorder to be treated or prevented. In some embodiments, a variant SAP polypeptide is administered to a patient once or twice per day, once or twice per week, once or twice per month, or just prior to or at the onset of symptoms.

[0115] Dosages may be readily determined by techniques known to those of skill in the art or as taught herein. Toxicity and therapeutic efficacy of SAP may be determined by standard pharmacological procedures in experimental animals, for example, determining the LD50 and the ED50. The ED50 (Effective Dose 50) is the amount of drug required to produce a specified effect in 50% of an animal population. The LD50 (Lethal Dose 50) is the dose of drug which kills 50% of a sample population.

[0116] In some embodiments, the SAP-responsive disorder is fibrosis. The use of SAP as a therapeutic treatment for fibrosis is described in U.S. Patent Application No. 2007/0243163, which is hereby incorporated by reference. Fibrosis related disorders that may be amenable to treatment with the subject method include, but are not limited to, collagen disease, interstitial lung disease, human fibrotic lung disease (e.g., obliterator bronchiolitis, idiopathic pulmonary fibrosis, pulmonary fibrosis from a known etiology, tumor stroma in lung disease, systemic sclerosis affecting the lungs, Hermansky-Pudlak syndrome, coal worker’s pneumoconiosis, asbestosis, silicosis, chronic pulmonary hypertension, AIDS-associated pulmonary hypertension, sarcoidosis, moderate to severe asthma and the like), fibrotic vascular disease, arterial sclerosis, atherosclerosis, varicose veins, coronary infarcts, cerebral infarcts, myocardial fibrosis, musculoskeletal fibrosis, post-surgical adhesions, human kidney disease (e.g., nephritic syndrome, Alport syndrome, HIV-associated nephropathy, polycystic kidney disease, Fabry’s disease, diabetic nephropathy, chronic glomerulonephritis, nephritis associated with systemic lupus, and the like), progressive systemic sclerosis (PSS), primary sclerosing cholangitis (PSC), liver fibrosis, liver cirrhosis, renal fibrosis, pulmonary fibrosis, cystic fibrosis, chronic graft versus host disease, scleroderma (local and systemic), Grave’s ophthalmopathy, diabetic retinopathy, glaucoma, Peyronie’s disease, penis fibrosis, urethrostenosis after cystectomy, inner accretion after surgery, scarring, myelofibrosis, idiopathic retroperitoneal fibrosis, peritoneal fibrosis from a known etiology, drug-induced fibrosis, incident to benign or malignant cancer, fibrosis incident to microbial infection (e.g., viral, bacterial, parasitic, fungal, etc.), Alzheimer’s disease, fibrosis incident to inflammatory bowel disease (including stricture formation in Crohn’s disease and microscopic colitis), stromal cell tumors, mucositis, fibrosis induced by chemical or environmental insult (e.g., cancer chemotherapy, pesticides, or radiation (e.g., cancer radiotherapy)).

[0117] In some embodiments, the fibrosis-related disorder is selected from systemic or local sclerosis, keloids, hypertrophic scars, atherosclerosis, restenosis, pulmonary inflammation and fibrosis, idiopathic pulmonary fibrosis, liver cirrhosis, fibrosis as a result of chronic hepatitis B or C infection, kidney disease, heart disease resulting from scar tissue, macular degeneration, and retinal and vitreal retinopathy. In some embodiments, the fibrosis-related disorder results from chemotherapeutic drugs, radiation-induced fibrosis, and injuries and burns. In some embodiments, the fibrosis-related disorder or condition results from post-surgical scarring, e.g., following trabeculectomy or other filtration surgery of the eye.

[0118] In some embodiments, the SAP-responsive disorder is a hypersensitivity disorder such as those mediated by Th1 or Th2 responses. The use of SAP as a therapeutic treatment for hypersensitivity disorders is also described in U.S. Provisional Application No. 61/209,795, which is hereby incorporated by reference. Hypersensitivity related disorders that may be amenable to treatment with SAP include, but are not limited to, allergic rhinitis, allergic sinusitis, allergic conjunctivitis, allergic bronchoconstriction, allergic dyspnea, allergic increase in mucous production in the lungs, atopic eczema, dermatitis, urticaria, anaphylaxis, pneumonitis, and allergic asthma.

[0119] In some embodiments, a variant SAP polypeptide of the invention may be used to treat allergen-specific immune
responses, such as anaphylaxis, to various antigens, including, but not limited to, antimicrobials (e.g., cephalosporins, sulfonamides, penicillin and other β-lactams), anticonvulsants (e.g., phenytoin, phenobarbital, carbamazepine, dapsone, allopurinol, and minocycline), chemotherapeutics (e.g., taxanes, platinum compounds, asparaginase, and epipodophyllotoxins), heparin, insulin, protamine, aspirin and other non-steroidal anti-inflammatory drugs, muscle relaxants (e.g., succinylcholine, atracurium, vecuronium, and pancuronium), induction agents (e.g., barbiturates, etomidate, propofol), narcotics (e.g., fentanyl, meperidine, morphine), coloids for intravascular volume expansion, radiocontrast materials, blood products, latex, animal products, animal dander, dust mites, insects (e.g., bites, stings or venom), cosmetics, metals (e.g., nickel, cobalt, and chromate), plants, spores, pollen, food (e.g., milk, eggs, wheat, soy, peanuts and tree nuts, seafood), vaccination, and fungal antigens (e.g., Aspergillus, Curvularia, Exserohilum, and Alternaria species).

[0120] In some embodiments, the SAP-responsive disorder is an autoimmune disorder such as those mediated by Th1 or Th2 responses. The use of SAP as a therapeutic treatment for autoimmune disorders is also described in U.S. Provisional Application No. 61/209,845, which is hereby incorporated by reference. Autoimmune related disorders that may be amenable to treatment with SAP include, but are not limited to, type 1 diabetes, multiple sclerosis, rheumatoid arthritis, psoriatic arthritis, autoimmune myocarditis, pemphigus, myasthenia gravis, Hashimoto’s thyroiditis, Graves’ disease, Addison’s disease, autoimmune hepatitis, chronic Lyme arthritis, familial dilated cardiomyopathy, juvenile dermatomyositis, polychondritis, Sjogren’s syndrome, psoriasis, juvenile idiopathic arthritis, inflammatory bowel disease, systemic lupus erythematosus, chronic obstructive pulmonary disease, and graft-versus-host disease.

[0121] In some embodiments, the SAP-responsive disorder is a mucosis. The use of SAP as a therapeutic treatment for mucosis is also described in U.S. application Ser. No. 12/217,614, which is hereby incorporated by reference. Methods of the invention may be useful for treating oral, esophageal, and gastrointestinal mucositis, as well as gastric and duodenal ulcers, or erosion of the stomach and esophagus.

[0122] In some embodiments, a variant SAP polypeptide of the invention may be used to treat an inflammatory disease or condition. In some embodiments, the inflammatory disease may be a viral, bacterial, fungal, or parasitic infection. The use of SAP as a therapeutic treatment for viral infection has also been described in U.S. Pat. No. 6,406,698 and in International Patent Application No. WO1997/026906, which are both incorporated by reference herein.

Pharmaceutical Preparations and Formulations

[0123] In certain embodiments, the methods described herein involve administration of at least one variant SAP polypeptide of the invention to a subject as a therapeutic agent. The therapeutic agents of the invention may be formulated in a conventional manner using one or more pharmaceutically acceptable carriers or excipients. For example, therapeutic agents and their pharmaceutically acceptable salts and solvates may be formulated for administration by, for example, injection (e.g. SubQ, IM, IP), inhalation or insufflation (either through the mouth or the nose) or oral, buccal, sublingual, transdermal, nasal, parenteral or rectal administra-
tion. In certain embodiments, therapeutic agents may be administered locally, at the site where the target cells are present, i.e., in a specific tissue, organ, or fluid (e.g., blood, cerebrospinal fluid, tumor mass, etc.).

[0124] The present invention further provides use of any variant SAP polypeptide of the invention in the manufacture of a medicament for the treatment or prevention of a disorder or a condition, as described herein, in a patient, for example, the use of a variant SAP polypeptide in the manufacture of medicament for the treatment of a disorder or condition described herein. In some aspects, any variant SAP polypeptide of the invention may be used to make a pharmaceutical preparation for the use in treating or preventing a disease or condition described herein.

[0125] Therapeutic agents can be formulated for a variety of modes of administration, including systemic and topical or localized administration. Techniques and formulations generally may be found in Remington’s Pharmaceutical Sciences, Meade Publishing Co., Easton, Pa. For parenteral administration, injection is preferred, including intramuscular, intravenous, intraperitoneal, and subcutaneous. For injection, the compounds can be formulated in liquid solutions, preferably in physiologically compatible buffers such as Hank’s solution or Ringer’s solution. In addition, the compounds may be formulated in solid form and dissolved or suspended immediately prior to use. Lyophilized forms are also included. In some embodiments, the therapeutic agents can be administered to cells by a variety of methods known to those familiar in the art, including, but not restricted to encapsulation in liposomes, by iontophoresis, or by incorporation into other vehicles, such as hydrogels, cycloextrins, biodegradable nanocapsules, and bioadhesive micro spheres.

[0126] For oral administration, the pharmaceutical compositions may take the form of, for example, tablets, lozenges, or capsules prepared by conventional means with pharmaceutically acceptable excipients such as binding agents (e.g., pregelatinized maize starch, polyvinylpyrrolidone or hydroxypropyl methylcellulose); fillers (e.g., lactose, microcrystalline cellulose or calcium hydrogen phosphate); lubricants (e.g., magnesium stearate, talc or silica); disintegrants (e.g., potato starch or sodium starch glycolate); or wetting agents (e.g., sodium lauryl sulphate). The tablets may be coated by methods well known in the art. Liquid preparations for oral administration may take the form of, for example, solutions, syrups or suspensions, or they may be presented as a dry product for constitution with water or other suitable vehicle before use. Such liquid preparations may be prepared by conventional means with pharmaceutically acceptable additives such as suspending agents (e.g., sorbitol syrup, cellulose derivatives or hydrogenated edible fats); emulsifying agents (e.g., lecithin or acacia); non-aqueous vehicles (e.g., almond oil, oily esters, ethyl alcohol or fractionated vegetable oils); and preservatives (e.g., methyl or propyl-p-hydroxybenzoates or sorbic acid). The preparations may also contain buffer salts, flavoring, coloring and sweetening agents as appropriate. Preparations for oral administration may be suitably formulated to give controlled release of the active compound.

[0127] For administration by inhalation (e.g., pulmonary delivery), therapeutic agents may be conveniently delivered in the form of an aerosol spray presentation from pressurized packs or a nebulizer, with the use of a suitable propellant, e.g., dichlorodifluoromethane, trichlorofluoromethane, dichlorotetrafluoroethane, carbon dioxide or other suitable gas. In
the case of a pressurized aerosol the dosage unit may be determined by providing a valve to deliver a metered amount. Capsules and cartridges of e.g., gelatin, for use in an inhaler or insufflator may be formulated containing a powder mix of the compound and a suitable powder base such as lactose or starch.

[0128] In the methods of the invention, the pharmaceutical compounds can also be administered by intranasal or intrabronchial routes including insufflation, powders, and aerosol formulations (for examples of steroid inhalants, see Rohatagi (1995) J. Clin. Pharmacology. 35:1187-1193; Tiwa (1995) Ann Allergy Asthma Immunol. 75:107-111). For example, aerosol formulations can be placed into pressurized acceptable propellants, such as dichlorodifluoromethane, propane, nitrogen, and the like. They also may be formulated as pharmaceutically for non-pressured preparations such as in a nebulizer or an atomizer. Typically, such administration is in an aqueous pharmacologically acceptable buffer.

[0129] Pharmaceutical compositions suitable for respiratory delivery (e.g., intranasal, inhalation, etc.) of variant SAP polypeptides may be prepared in either solid or liquid form.

[0130] SAP polypeptides of the invention may be formulated for parenteral administration by injection, e.g., by bolus injection or continuous infusion. Formulations for injection may be presented in unit dosage form, e.g., in ampoules or in multi-dose containers, with an added preservative. The compositions may take such forms as suspensions, solutions or emulsions in oily or aqueous vehicles, and may contain formulatory agents such as suspending, stabilizing and/or dispersing agents. Alternatively, the active ingredient may be in powder form for constitution with a suitable vehicle, e.g., sterile pyrogen-free water, before use.

[0131] In addition, SAP polypeptides of the invention may also be formulated as a depot preparation. Such long-acting formulations may be administered by implantation (for example subcutaneously or intramuscularly) or by intramuscular injection. Thus, for example, therapeutic agents may be formulated with suitable polymeric or hydrophobic materials (for example an emulsion in an acceptable oil) or ion exchange resins, or as sparingly soluble derivatives, for example, as a sparingly soluble salt. Controlled release formula also includes patches.

[0132] In certain embodiments, the compounds described herein can be formulated for delivery to the central nervous system (CNS) (reviewed in Begley, Pharmacology & Therapeutics 104: 29-45 (2004)). Conventional approaches for drug delivery to the CNS include: neurosurgical strategies (e.g., intracerebral injection or intracerebroventricular injection); molecular manipulation of the agent (e.g., production of a chimeric fusion protein that comprises a transport peptide that has an affinity for an endothelial cell surface molecule in combination with an agent that is itself incapable of crossing the blood-brain-barrier in an attempt to exploit one of the endogenous transport pathways of the blood-brain-barrier); pharmacological strategies designed to increase the lipid solubility of an agent (e.g., conjugation of water-soluble agents to lipid or cholesterol carriers); and the transitory disruption of the integrity of the BBB by hyperosmotic disruption (resulting from the infusion of a mannitol solution into the carotid artery or the use of a biologically active agent such as an angiotensin peptidase).

[0133] In certain embodiments, SAP polypeptides of the invention are incorporated into a topical formulation containing a topical carrier that is generally suited to topical drug administration and comprising any such material known in the art. The topical carrier may be selected so as to provide the composition in the desired form, e.g., as an ointment, lotion, cream, microemulsion, gel, oil, solution, or the like, and may be comprised of a material of either naturally occurring or synthetic origin. It is preferable that the selected carrier not adversely affect the active agent or other components of the topical formulation. Examples of suitable topical carriers for use herein include water, alcohols and other nontoxic organic solvents, glycerin, mineral oil, silicone, petroleum jelly, lanolin, fatty acids, vegetable oils, parabens, waxes, and the like.

[0134] Pharmaceutical compositions (including cosmetic preparations) may comprise from about 0.00001 to 100% such as from 0.001 to 10% or from 0.1% to 5% by weight of one or more of the variant SAP polypeptides described herein. In certain topical formulations, the active agent is present in an amount in the range of approximately 0.25 wt. % to 75 wt. % of the formulation, preferably in the range of approximately 0.25 wt. % to 30 wt. % of the formulation, more preferably in the range of approximately 0.5 wt. % to 15 wt. % of the formulation, and most preferably in the range of approximately 1.0 wt. % to 10 wt. % of the formulation.

[0135] Conditions of the eye can be treated or prevented by e.g., systemic, topical, intraocular injection of therapeutic agents, or by insertion of a sustained release device that releases therapeutic agents. SAP polypeptides of the invention may be delivered in a pharmaceutically acceptable ophthalmic vehicle, such that the compound is maintained in contact with the ocular surface for a sufficient time period to allow the compound to penetrate the corneal and internal regions of the eye, as for example the anterior chamber, conjunctiva, posterior chamber, vitreous body, aqueous humor, vitreous humor, cornea, iris/ciliary, lens, choroid/retina and sclera. The pharmaceutically acceptable ophthalmic vehicle may, for example, be an ointment, vegetable oil or an encapsulating material. Alternatively, the compounds may be injected directly into the vitreous and aqueous humour. In a further alternative, the compounds may be administered systemically, such as by intravenous infusion or injection, for treatment of the eye.

[0136] Therapeutic agents described herein may be stored in oxygen-free environment according to methods in the art.

[0137] Exemplary compositions comprise an SAP polypeptide with one or more pharmaceutically acceptable carriers and, optionally, other therapeutic ingredients. The carrier(s) must be “pharmaceutically acceptable” in the sense of being compatible with the other ingredients of the composition and not eliciting an unacceptable deleterious effect in the subject. Such carriers are described herein or are otherwise well known to those skilled in the art of pharmacology.

In some embodiments, the pharmaceutical compositions are pyrogen-free and are suitable for administration to a human patient. In some embodiments, the pharmaceutical compositions are irritant-free and are suitable for administration to a human patient. In some embodiments, the pharmaceutical compositions are allergen-free and are suitable for administration to a human patient. The compositions may be prepared by any of the methods well known in the art of pharmacy.

[0138] In some embodiments, an SAP polypeptide is administered in a time release formulation, for example in a composition which includes a slow release polymer. An SAP polypeptide can be prepared with carriers that will protect against rapid release. Examples include a controlled release vehicle, such as a polymer, microencapsulated delivery sys-
tem, or bioadhesive gel. Alternatively, prolonged delivery of an SAP polypeptide may be achieved by including in the composition agents that delay absorption, for example, aluminum monostearate hydrogels and gelatin.

[0139] Methods for delivering nucleic acid compounds are known in the art (see, e.g., Akhtar et al., 1992, Trends Cell Bio., 2, 139; and Delivery Strategies for Antisense Oligonucleotide Therapeutics, ed. Akhtar, 1995; Sullivan et al., International Application No. WO 94/02595). These protocols can be utilized for the delivery of virtually any nucleic acid compound. Nucleic acid compounds can be administered to cells by a variety of methods known to those familiar to the art, including, but not restricted to, encapsulation in liposomes, by iontophoresis, or by incorporation into other vehicles, such as hydrogels, cyclodextrins, biodegradable nanocapsules, and bioadhesive microspheres. Alternatively, the nucleic acid/vehicle combination is locally delivered by direct injection or by use of an infusion pump. Other routes of delivery include, but are not limited to, oral (tablet or pill form) and/or intrathecal delivery (Gold, 1997, Neuroscience, 76, 1153-1158). Other approaches include the use of various transport and carrier systems, for example though the use of conjugates and biodegradable polymers. For a comprehensive review on drug delivery strategies, see Ho et al., 1999, Curr. Opin. Mol. Ther., 1, 336-343 and Jain, Drug Delivery Systems: Technologies and Commercial Opportunities, Decision Resources, 1998 and Groothuis et al., 1997, J. Neuro Virol., 3, 387-400. More detailed descriptions of nucleic acid delivery and administration are provided in Sullivan et al., supra, Draper et al., PCT WO93/23569, Beigelman et al., International Application No. WO99/05094, and Klimuk et al., International Publication No. WO99/04819.

[0140] The following examples serve to more fully describe the manner of using the above-described invention, as well as to set forth the best modes contemplated for carrying out various aspects of the invention. It is understood that these examples in no way serve to limit the true scope of this invention, but rather are presented for illustrative purposes.

**EXEMPLIFICATION**

**Example 1**
Recombinant SAP is More Potent than Human Serum-Derived SAP

[0141] Recombinant human SAP isolated from CHO—S cells (rhSAP) and human serum-derived SAP (hSAP) were assayed for bioactivity using an in vitro bioassay. In this assay, monocyte enriched Peripheral Blood Mononuclear Cells (PBMCs) were incubated with varying concentrations of either rhSAP or hSAP for 96 hours. Following this incubation, resulting culture supernatants were removed and assayed by ELISA to quantify the amount of Macrophage Derived Chemokine (MDC) that was produced. MDC is produced by fibrocytes and therefore an indicator of monocyte differentiation into fibrocytes. By comparing the inhibitory concentration, 50% (IC_{50}) of the sample to the hSAP reference standard, the relative potency of a SAP glycovariant can be determined. The result is expressed as an IC_{50} ratio of the sample versus the hSAP reference standard.

[0142] All SAP samples and standards were initially diluted to a concentration of 1.0 mg/mL in Supplemented FibroLife Media. SAP standards were serially diluted to generate working standard concentrations of 60, 30, 20, 13.4, 8.8, 6.0, 3.0, 1.5, and 0.75 µg/mL (final standard concentration of 30, 15, 10, 6.7, 4.4, 3.0, 1.5, 0.75, and 0.375 µg/mL) See the following Table 1.

[0143] To prepare for the ELISA assay, the capture antibody (i.e., mouse anti-human MDC) was diluted to the working concentration in PBS without carrier protein. The diluted capture antibody was used to coat 96-well plates, and then each plate was sealed and incubated overnight at room temperature. Before using the coated plates, each well was aspirated and washed with wash buffer, repeating the process two times for a total of three washes. The plates were then blocked by adding 300 µL of reagent diluent to each well and incubating at room temperature for one hour. After incubation the aspiration and well-washing procedure was repeated.

[0144] For the ELISA assay, 100 µL samples of either the supernatants from the monocyte/fibrocyte cultures or the SAP standards were added to each well. The plate was then incubated at room temperature for 2 hours before aspirating and washing the wells. Then 100 µL of a working dilution of Streptavidin-HRP was added to each well. The plate was incubated for 20 minutes at room temperature before adding 50 µL of Stop Solution to each well. Immediately, the optical density of each well was measured using a microplate reader set to 450 nm. If wavelength correction was available, the microplate reader was set to 540 nm or 570 nm. If wavelength correction was not available, then the readings at 540 nm or 570 nm were subtracted from the readings at 450 nm. This subtraction corrects for optical imperfections in the plate.

[0145] Both rHISAP and hSAP were assayed for bioactivity using this assay (FIG. 1). On average, rHISAP is 3.4-fold more active than hSAP (average of 7 independent experiments).

**Example 2**

**Modification of SAP Glycan Structures**

[0146] Using in vitro glycoremodeling techniques, glycan moieties on a sample of recombinant human SAP (rSAP) were modified to replace terminal α-2,3-linked sialic acid moieties with α-2,6-linked sialic acid moieties (FIG. 2, A and B). Similarly, a sample of human serum-derived SAP (hSAP) was also modified to replace terminal α-2,6-linked sialic acid moieties with α-2,3-linked sialic acid moieties (FIG. 2, C and D). In addition, as rSAP isolated from CHO—S cells is only partially sialylated, a sample of rSAP was treated to fully sialylate the attached glycan structures with α-2,3-linked sialic acid moieties (FIG. 2, E and F).
Both rhSAP and hSAP (Calbiochem Cat#970549) were treated with a α-2,3,6,8-sialidase (Sigma Cat #N8271) to fully desialylate the polypeptides. After sialidase treatment for 17 hours, desialylated (i.e. asialo) rhSAP and hSAP were purified using phosphoethanolamine (PE) affinity and size exclusion (Sephadex 200 prep grade) chromatography. Purified asialo SAP polypeptides were then enzymatically treated using either α-2,3- or α-2,6-sialyltransferases (Calbiochem Cat #566223) in the presence of CMP-sialic acid (Calbiochem Cat #233264) for 17 hours at 37°C. The following tables provide details on each reaction mixture.

[0149] After sialylation treatment, both sialylated rhSAP and hSAP variants were purified using PE affinity chromatography followed by dialysis into 10 mM NaPi/5% sorbitol pH 7.5 (P5S buffer). Confirmation of the desired sialic acid linkages (i.e., α-2,3-linked hSAP and α-2,6-linked rhSAP) was performed using both Liquid Chromatography Mass Spectrometry (FIG. 2; A, C, and E) and Anion-Exchange High Performance Liquid Chromatography (FIG. 2; B, D, and F) following treatment of the glycovariant SAP polypeptides with α-2,3 sialidase (CalBiochem Cat#480706) at 37°C for 24 hours.

Example 3
In Vitro Bioassays to Determine Sap Glycovariant Potency for Inhibiting Monocyte Differentiation into Fibrocytes

[0150] Glycoengineered rhSAP and hSAP were assayed for bioactivity using the same in vitro bioassay described in Example 1. In brief, monocyte enriched peripheral blood mononuclear cells (PBMCs) were incubated with varying concentrations of an SAP polypeptide for 96 hours. Following this incubation, resulting culture supernatants were removed and assayed by ELISA to quantify the amount of Macrophage Derived Chemokine (MDC) that was produced. The results were expressed as an IC_{50} ratio of the sample versus the hSAP reference standard and plotted as relative activity (relative activity of hSAP=1). All α-2,3-sialic acid linkage containing test materials are ≥2.4-fold more active than hSAP (FIG. 3). Equal mixtures of α-2,3- and α-2,6-linked sialic acid derivatives of SAP show intermediate activity levels between 100% α-2,6-linked and 100% α-2,3-linked SAP as expected (two rightmost bars in FIG. 3).

[0151] An alternative method of quantifying fibrocyte differentiation involves directly enumerating the number of fibrocytes that are generated after monocytes are incubated with a fibrocyte suppressant (e.g., SAP or variant thereof) or activating agent (e.g., M-CSF). In one experiment, monocytes were purified from whole blood-derived PBMC using negative magnetic bead selection standard in the art (e.g., CAT#113-41D, Invitrogen, Carlsbad, Calif.) and cultured in a 96-Well tissue culture plate containing FibroLife Media supplemented with 25 or 50 ng/mL of M-CSF in triplicate. The plate was incubated for 96 hours at 37°C in a 5% CO_2 incubator. The cells were then fixed with parafomaldehyde and stained with Hema 3 stain (Cat#122-911, Hema 3 Stain, Fisher Scientific, Hampton, N.H.). The number of fibrocytes per well were determined by summing the count of different fields per well using an inverted microscope. Fibrocytes were defined morphologically as adherent cells with an elongated spindle-shape and the presence of an oval nucleus.

The data indicated that either 25 or 50 ng/mL of M-CSF was sufficient to increase the number of fibrocytes differentiating from monocytes by ~50% in this donor (FIG. 4). Subsequent experiments used FibroLife Media supplemented with 25 ng/mL of M-CSF as needed and defined below.

[0152] FibroLife Media: (Cat # LM-0001, Lifeline Cell Technology, Walkersville, Md.) supplemented with 10 mM HEPES (Cat # H8087, Sigma-Aldrich), 1× non-essential amino acids (Cat # M7145, Sigma-Aldrich), 1 mM sodium pyruvate (Cat # S8636, Sigma-Aldrich), 2 mM glutamine (Cat # 25030-487, Invitrogen), 100 U/mL penicillin and 100 µg/mL streptomycin (Cat # 07801, Sigma-Aldrich), and ITS-3 (Cat # 12771.500 µg/mL bovine serum albumin, 10 µg/mL insulin, 5 µg/mL transferrin, 5 µg/mL sodium selenite, 5 µg/mL linoleic acid, and 5 µg/mL oleic acid, Sigma-Aldrich).
In an additional experiment, PBMC or monocytes were purified from whole blood and cultured in FibroLife Media supplemented with various amounts of SAP in triplicate (as described above). The plate was incubated for 96 hours at 37°C in a 5% CO₂ incubator. The cells were then fixed with paraformaldehyde and stained with Hematoxylin stain. The number of fibrocytes per well were determined by summing the count of five different fields per well using an inverted microscope. The minimum concentration of SAP necessary to provide maximum inhibition of fibrocyte differentiation in this system was determined to be 2 µg/ml (FIG. 5). The number of fibrocytes decreases with increasing SAP concentration in all donors.

<213> ORGANISM: Gallus gallus

INCORPORATION BY REFERENCE

All publications and patents mentioned herein are hereby incorporated by reference in their entirety as if each individual publication or patent was specifically and individually indicated to be incorporated by reference.

While specific embodiments of the subject matter have been discussed, the above specification is illustrative and not restrictive. Many variations will be apparent to those skilled in the art upon review of this specification and the below-listed claims. The full scope of the invention should be determined by reference to the claims, along with their full scope of equivalents, and the specification, along with such variations.

We claim:

1. A glycosylated human Serum Amyloid P (SAP) polypeptide comprising an N-linked oligosaccharide chain, wherein at least one branch of the oligosaccharide chain terminates with a α-2,3-linked sialic acid moiety.

2. A glycosylated human SAP polypeptide comprising an N-linked oligosaccharide chain, wherein the oligosaccharide chain has at least 50% fewer α-2,6-linked sialic acid moieties than wild-type SAP isolated from human serum.

3. The glycosylated human SAP polypeptide of claim 1, wherein all branches of the oligosaccharide chain terminate with α-2,3-linked sialic acid moieties.

4. The glycosylated human SAP polypeptide of claim 1, wherein the oligosaccharide chain is substantially free of α-2,6-linked sialic acid moieties.

5. The glycosylated human SAP polypeptide of claim 1, wherein the polypeptide comprises an amino acid sequence at least 95% identical to SEQ ID NO: 1.

6. The glycosylated human SAP polypeptide of claim 1, wherein the polypeptide is a fusion protein comprising an SAP domain and one or more heterologous domains.

7. The glycosylated human SAP polypeptide of claim 1, wherein the polypeptide comprises one or more modified amino acid residues.
8. The glycosylated human SAP polypeptide of claim 7, wherein the one or more modified amino acid residues comprise a PEGylated amino acid, a prenylated amino acid, an acetylated amino acid, a biotinylated amino acid, and/or an amino acid conjugated to an organic derivatizing agent.

9. The glycosylated human SAP polypeptide of claim 1, wherein the SAP polypeptide has an IC₅₀ for inhibiting the differentiation of monocytes into fibroblasts in vitro that is less than one-half that of a corresponding sample of wild-type SAP isolated from human serum.

10. A pharmaceutical preparation suitable for use in a mammal comprising the human SAP polypeptide of claim 1 and a pharmaceutically acceptable carrier.

11. A method of treating or preventing a disorder or condition in a patient, the method comprising administering to a patient in need thereof a therapeutically effective amount of the SAP polypeptide of claim 1, wherein the disorder or condition is selected from a fibrotic or fibroproliferative disorder or condition, a hypersensitivity disorder or condition, an autoimmune disorder or condition, an inflammatory disorder or condition, and mucositis.

12. A method of making a human SAP polypeptide, comprising:
   i) expressing a human SAP polypeptide in a CHO cell; and
   ii) isolating the human SAP polypeptide from the cell.

13. The method of claim 12, wherein the isolated SAP polypeptide comprises an N-linked oligosaccharide chain, and wherein at least one branch of the oligosaccharide chain terminates with an α-2,3-linked sialic acid moiety.

14. The method claim 12, wherein the isolated SAP polypeptide comprises an N-linked oligosaccharide chain, and wherein the oligosaccharide chain has at least 50% fewer α-2,6-linked sialic acid moieties than wild-type SAP isolated from human serum.

15. The method of claim 12, wherein the isolated human SAP polypeptide has an IC₅₀ for inhibiting the differentiation of monocytes into fibroblasts in vitro that is less than one-half that of a corresponding sample of wild-type SAP isolated from human serum.

16. The method of claim 12, further comprising enzymatically or chemically altering the isolated SAP polypeptide to produce an SAP polypeptide having a modified oligosaccharide chain.

17. The method of claim 16, wherein the process of enzymatically or chemically altering the isolated SAP polypeptide removes one or more terminal α-2,6-linked sialic acid moieties from the oligosaccharide chain.

18. The method of claim 16, wherein the process of enzymatically or chemically altering the isolated SAP polypeptide replaces one or more terminal α-2,6-linked sialic acid moieties on the oligosaccharide chain with one or more α-2,3-linked sialic acid moieties.

19. A method of making an SAP polypeptide, comprising:
   i) providing an SAP polypeptide, and
   ii) enzymatically or chemically altering the SAP polypeptide to produce a glycosylated SAP polypeptide comprising an N-linked oligosaccharide.

20. The method of claim 19, wherein the N-linked oligosaccharide chain has at least 50% fewer α-2,6-linked sialic acid moieties than a wild-type human SAP protein isolated from human serum.

21. The method of claim 19, wherein at least one branch of the oligosaccharide chain terminates in an α-2,3-linked sialic acid moiety.

22. The human SAP polypeptide of claim 19, wherein the glycosylated SAP polypeptide has an IC₅₀ for inhibiting the differentiation of monocytes into fibroblasts in vitro that is less than one-half that of a corresponding sample of wild-type SAP isolated from human serum.

23. A human SAP polypeptide prepared by a process comprising:
   i) expressing a SAP polypeptide in a CHO cell; and
   ii) isolating the SAP polypeptide from the cell.

24. The human SAP polypeptide of claim 23, wherein the SAP polypeptide has an IC₅₀ for inhibiting the differentiation of monocytes into fibroblasts in vitro that is less than one-half that of a corresponding sample of wild-type SAP isolated from human serum.

25. A CHO cell comprising a nucleic acid encoding an exogenous SAP polypeptide.

26. A human SAP polypeptide having an IC₅₀ for inhibiting the differentiation of monocytes into fibroblasts in vitro that is less than one-half that of a corresponding sample of wild-type SAP isolated from human serum.
