ADDITIVELY MANUFACTURED ROTOR BLADES AND COMPONENTS

FIELD OF THE INVENTION

[0001] The present subject matter generally relates to additive manufacturing methods of joining two components along an interlocking transition zone.

BACKGROUND OF THE INVENTION

[0002] In manufacturing, it is often desirable to join two or more components to create a single part. However, current methods of joining components, whether these components are made from the same or dissimilar materials, often result in poor mechanical properties.

[0003] For example, prior art methods of joining two components may include metal-melting processes such as welding or brazing, using mechanical fasteners such as rivets or screws, or applying and curing a structural adhesive. These joints can exhibit poor physical properties and provide a weak mechanical bond, such as poor shear bonding or adhesion. These joints may also be prone to crack initiation and propagation along the material transition line or plane due to concentrated stresses in those regions.

[0004] In addition, in some applications, it is desirable to have a joint that allows some relative movement between joined components. For example, a joint between two or more components that is not pliant or flexible may exhibit issues related to fatigue durability, impact resistance, and overall lifetime of the joint. In cases where the components or joining material have different coefficients of thermal expansion, a joint that allows no relative movement cannot compensate for thermal growth mismatch, thus leading to failure of the joint in certain temperature environments.

[0005] Additionally, cooling holes that extend between joined components may be desirable. However, depending on the orientation and configuration of the joint and components, it may not be possible to form cooling holes using current methods, such as drilling or machining, without compromising the integrity of the joint. It may not be

276362B

possible to create a cooling hole, for example, where the hole is internal to the joint itself or where drilling a hole might otherwise weaken the joint.

[0006] Accordingly, a method of joining two or more components with improved structural integrity is desirable. More particularly, a method for forming a joint that allows for relative movement between components or the inclusion of cooling holes if desired, while still providing a strong mechanical bond would be particularly useful.

BRIEF DESCRIPTION OF THE INVENTION

[0007] Aspects and advantages of the invention will be set forth in part in the following description, or may be obvious from the description, or may be learned through practice of the invention.

[0008] In one exemplary embodiment of the present disclosure, a rotor blade formed via additive manufacturing is provided. The rotor blade includes an airfoil and a coupled component. The airfoil includes a plurality of fused layers of a first material formed via additive manufacturing and defines a leading edge and a tip at a distal end. The coupled component includes a plurality of fused layers of a second material formed via additive manufacturing. An interlocking transition zone includes a plurality of projections alternately extending from the airfoil and the coupled component, respectively, to undetachably couple the airfoil and the coupled component.

[0009] In still another embodiment of the present disclosure, a method of forming a rotor blade using additive manufacturing is provided. The method includes fusing a plurality of layers of a first material via additive manufacturing to form an airfoil, wherein the airfoil defines a leading edge and a tip at a distal end. The method also includes fusing a plurality of layers of a second material via additive manufacturing to form a coupled component. The method also includes undetachably coupling the airfoil and the coupled component by forming an interlocking transition zone comprising a plurality of projections alternately extending from the airfoil and the coupled component, respectively.

276362B

[0010] These and other features, aspects and advantages of the present invention will become better understood with reference to the following description and appended claims. The accompanying drawings, which are incorporated in and constitute a part of this specification, illustrate embodiments of the invention and, together with the description, serve to explain the principles of the invention.

BRIEF DESCRIPTION OF THE DRAWINGS

[0011] A full and enabling disclosure of the present invention, including the best mode thereof, directed to one of ordinary skill in the art, is set forth in the specification, which makes reference to the appended figures, in which:

[0012] FIG. 1 is a perspective view of an interlocking transition zone in accordance with an example embodiment of the present disclosure, where the first and second components are shown separated to provide a clear view of the projections;

[0013] FIG. 2 is a side view of an interlocking transition zone with shaft and knob projections according to an example embodiment;

[0014] FIG. 3 is a side view of an interlocking transition zone with trapezoidal projections according to an example embodiment;

[0015] FIG. 4 is a side view of an interlocking transition zone with elongated shaft and knob projections according to an example embodiment;

[0016] FIG. 5 is a side view of an interlocking transition zone with shaft and knob projections, where a braze material is used as an adhesive between the first and second component according to an example embodiment;

[0017] FIG. 6 is a side view of a non-planar interlocking transition zone with a cooling hole extending through according to an example embodiment;

276362B

[0018] FIG. 7 is a perspective cross-sectional view of an interlocking transition zone with a cooling hole extending through according to an example embodiment;

[0019] FIG. 8 is a schematic cross-sectional view of a gas turbine engine according to an exemplary embodiment of the present subject matter;

[0020] FIG. 9A is a top view of a rotor blade having an airfoil including a protective airfoil tip undetachably coupled to a distal end of the airfoil according to an example embodiment;

[0021] FIG. 9B is a top view of a rotor blade having an airfoil including a retractable, protective airfoil tip undetachably coupled to the distal end of the airfoil according to an example embodiment;

[0022] FIG. 10 is a top view of a rotor blade having an airfoil including a protective leading edge undetachably coupled to a leading edge of the airfoil according to an example embodiment; and

[0023] FIG. 11 is a top view of a rotor blade having an airfoil including an integral, under-platform damper undetachably coupled to a radially inner surface of an airfoil platform according to an example embodiment.

[0024] Repeat use of reference characters in the present specification and drawings is intended to represent the same or analogous features or elements of the present invention.

DETAILED DESCRIPTION OF THE INVENTION

[0025] Reference now will be made in detail to embodiments of the invention, one or more examples of which are illustrated in the drawings. Each example is provided by way of explanation of the invention, not limitation of the invention. In fact, it will be apparent to those skilled in the art that various modifications and variations can be made in the present invention without departing from the scope of the invention. For instance, features illustrated or described as part of one embodiment can be used with another embodiment

276362B

to yield a still further embodiment. Thus, it is intended that the present invention covers such modifications and variations as come within the scope of the appended claims and their equivalents.

[0026] Additive manufacturing technology enables fabrication of complex objects by building objects point-by-point, layer-by-layer, typically in a vertical (Y) direction. Although the discussion below refers to the addition of material, one skilled in the art will appreciate that the methods and structures disclosed herein may be practiced with any additive manufacturing technique or technology. For example, embodiments of the present invention may use layer-additive processes, layer-subtractive processes, or hybrid processes. In some embodiments, the method and structure disclosed herein may provide two or more components joined by an interlocking transition zone 10 and formed by successively depositing layers of one or more materials.

[0027] Embodiments of the present disclosure provide methods and structures for joining two or more components using additive manufacturing technology. In this regard, multiple components may be created that are independent entities, but that are created with interlocking features in their construction to effectively form mechanical “roots” that reach across a bonding region, thereby resisting disassembly and carrying structural loading across the transition zone. The resulting joints may be planar or non-planar and may exhibit improved mechanical strength and adhesion. The interlocking material transition zone can also be used, for example, to secure a highly impact resistant protective coating layer to a base material. In addition, the interlocking features may be spaced apart to permit a small range of motion between the components, and the joints may have integrated cooling holes or passageways.

[0028] Referring now to the figures, FIG. 1 shows a perspective view of an interlocking transition zone 10 in accordance with an example embodiment of the present disclosure, where a first component 12 and a second component 14 are shown separated to provide a clear view of a plurality of projections 16. As shown, the interlocking transition zone 10 may extend in the in a planar region defined by the X-Z plane. Notably, only the

276362B

interlocking transition zone 10 is shown in the figures, but one skilled in the art will appreciate that the first component 12 and second component 14 can be any simple or complex object manufactured using additive manufacturing technology. In addition, the first component 12 and second component 14, and the interlocking transition zone 10 connecting them, can be scaled to any size. For example, each projection 16 might range from several nanometers in cross-section to several centimeters or larger. Given its versatility and scalability, the presently disclosed method and structure for joining two or more components using additive manufacturing technology can be practiced in various applications and fields of technology.

[0029] FIG. 2 is a side view of an interlocking transition zone 10 with shaft 18 and knob 20 projections 16 according to one exemplary embodiment. As shown, each of the first component 12 and second component 14 comprises a plurality of projections 16 extending from a first component surface 22 and a second component surface 24, respectively. Although the illustrated embodiment shows each projection 16 extending in a substantially perpendicular direction, one skilled in the art will appreciate that in other embodiments, each projection 16 may be fabricated at any angle with respect to the component surfaces 22, 24. Each projection 16 comprises a shaft 18 with a knob 20 located at its distal end. In the embodiments illustrated in FIGS. 1 and 2, the shaft 18 is cylindrical and the knob 20 is spherical. However, in some embodiments, the shaft 18 may instead have a cross-section that is square, rectangular, elliptical, irregularly shaped, or any other suitable shape, and may be at common or at different lengths. Similarly, the knob 20 may be square, oblong, or any other suitable shape.

[0030] The plurality of projections 16 may alternately extend from the first component 12 and the second component 14 to form an interlocking transition zone 10 extending in both the longitudinal (X) and lateral (Z) direction. In some embodiments, the diameter of knob 20 is larger than the diameter of shaft 18, and the shafts 18 are spaced along the first component 12 and second component 14 such that the knob 20 may fit between adjacent shafts 18. In this manner, the plurality of projections 16 form an interlocking transition

276362B

zone 10 that mechanically couples the first component 12 and the second component 14. Because the interlocking transition zone 10 may be printed layer-by-layer using additive manufacturing, the resulting interlocking transition zone 10 undetachably couples the first component 12 and the second component 14. In this regard, the first component 12 and the second component 14 are joined such that they may not be separated through non-destructive means. In some embodiments, at least a portion of adjacent projections 16 may prevent relative motion between the components 12, 14. As explained in more detail below, in other embodiments the spacing of the shafts 18 may be adjusted to allow for relative movement of the plurality of projections 16 and provide some flexibility to the interlocking transition zone 10.

[0031] In some example embodiments, the projections 16 can have a different shape. In this regard, the plurality of projections 16 may be irregularly shaped, and each projection 16 may either fill the entire area between adjacent projections 16, or may leave gaps or small interstices 26. For example, as shown in FIG. 3, the projections 16 may be trapezoidal projections 28. In this regard, each trapezoidal projection 28 has a narrow cross-section proximate to the first component 12 or second component 14, respectively. The cross-sectional area of the trapezoidal projection 28 gets larger as the trapezoidal projection 28 extends away from the first component 12 or second component 14 toward a distal end of the trapezoidal projection 28, where the cross-section is the largest.

[0032] Referring now specifically to the embodiment of FIG. 4, the plurality of projections 16 may be elongated projections 30. In this regard, the elongated projections 30 may have elongated shafts 32, or may be otherwise fabricated to allow some relative motion between the first component 12 and the second component 14. For example, the elongated shafts 32 may allow the first component 12 and second component 14 to slide relative to each other in the Z-direction (as indicated by arrow 34) until the adjacent knobs 20 come into contact with each other. Similarly, in some embodiments, the spacing of the plurality of projections 16 may be increased so as to permit a small range of motion in the X, Y, and Z planes and rotations about the X, Y, and Z axis. As one skilled in the art will

276362B

appreciate, the size, shape, and spacing of the plurality of projections 16 may be adjusted to permit or restrict motion as needed for any particular application.

[0033] Now referring specifically to FIG. 5, some embodiments of the interlocking transition zone 10 may have an adhesive 36 or other material disposed between the first component surface 22 and the second component surface 24 in order to further ensure a strong bond. This adhesive layer 36 may be, for example, an epoxy or cured resin, or the joint may be made by introduced a brazing filler material between the first component 12 and second component 14. Alternatively, the adhesive layer 36 may be another additively manufactured layer between the first component 12 and the second component 14, and may be made from any material suitable for use in an additive manufacturing process, as discussed below. In this manner, the adhesive layer 36 may improve the mechanical bond strength of the interlocking transition zone 10.

[0034] In some cases, it is desirable to include cooling holes 38 that extend through the interlocking transition zone 10 to provide for communication of cooling fluid between the first component 12 and second component 14 and/or within the interlocking transition zone 10. FIG. 6 shows a side view of a non-planar interlocking transition zone 10 with an integrated cooling hole 38. FIG. 7 is a perspective cross-sectional view of an interlocking transition zone 10 with an integrated cooling hole 38. In these exemplary embodiments, the cooling holes 38 may be formed through the components by selectively depositing material during the additive manufacturing process to form the passageway or cooling hole 38. The cooling holes 38 may extend internally through an interlocking transition zone 10, such that they are self-contained and not exposed to any exterior surface of the joined components. In addition, the cooling holes 38 may be of any shape or size, and may be placed in any location. For example, although the cooling holes 38 depicted in FIGS. 6 and 7 are linear and extend straight through the interlocking transition zone 10 from the first component 12 to the second component 14, the cooling holes 38 may instead be curved or serpentine.

276362B

[0035] The additive manufacturing process disclosed herein enables the first component 12 and second component 14 to be made of any of a variety of materials. Each component may be made of the same material or of a different material. In fact, even a single component may comprise multiple layers of different materials. In some embodiments, the first component 12 may be a first part and the second component 14 may be a second part, such that the interlocking transition zone 10 creates a multi-part assembly. Moreover, one skilled in the art will appreciate that the method and structure described herein need not be limited to two components, but may be used to join more than two components. In some embodiments, the first component 12 may be a base material and the second component 14 may be a protective coating. For example, the second component 14 may be a thermal barrier coating or a bond coat of thermal barrier coating to provide improved thermal durability to the first component 12. In other embodiments, the protective coating may be a very durable material exhibiting high impact resistance. In this manner, the protective coating may protect the underlying component from impact damage and extend its lifetime.

[0036] As indicated above, the second component 14 may be a protective coating, such as a thermal barrier coating (TBC) system or an environmental barrier coating (EBC) system. Such TBC and EBC systems may generally include a bond layer covering the outer surface of the first component 12 and a thermal barrier layer disposed over the bond layer. As is generally understood, the bond layer may be formed from an oxidation resistant metallic material designed to inhibit oxidation and/or corrosion of the underlying first component 12. For instance, in several embodiments, the bond layer may be formed from a material comprising "MCrAlY," where "M" represents iron, nickel or cobalt, or from an aluminide or noble metal aluminide material (e.g., platinum aluminide). Similarly, the thermal barrier layer may be formed from a temperature resistant material in order to increase the operating temperature capability of the first component 12. For example, in several embodiments, the thermal barrier layer may be formed from various known ceramic materials, such as zirconia partially or fully stabilized by yttrium oxide, magnesium oxide or other noble metal oxides.

276362B

[0037] Moreover by using the methods and structures disclosed above to create an interlocking transition zone 10, the bond layer of the TBC and EBC systems may be eliminated altogether. In this regard, the bond layer is typically used in TBC and EBC systems in order to provide an intermediate layer between the first component 12 and the thermal barrier coating to compensate for thermal mismatching—i.e., the first component 12 and thermal barrier coating may have different coefficients of thermal expansion, causing stresses as the materials grow at different rates when placed in high temperature environments. The bond layer provides additional mechanical strength and adhesion to ensure the thermal mismatching does not result in bonding region failure. However, as discussed above, the plurality of projections 16 form an interlocking transition zone 10 that provides a strong mechanical bond and improved adhesion between components. Therefore, if an interlocking transition zone 10 couples a protective thermal barrier coating to the first component 12, the bond layer may be eliminated altogether and the assembly can still withstand high temperature environments.

[0038] In addition, one skilled in the art will appreciate that a variety of materials and methods for bonding those materials may be used and are contemplated as within the scope of the present disclosure. For example, the material may be plastic, metal, concrete, ceramic, polymer, epoxy, photopolymer resin, or any other suitable material that may be in solid, liquid, powder, sheet material, or any other suitable form. As used herein, references to “fusing” may refer to any suitable process for creating a bonded layer of any of the above materials. For example, if an object is made from polymer, fusing may refer to creating a thermoset bond between polymer materials. If the object is epoxy, the bond may be formed by a crosslinking process. If the material is ceramic, the bond may be formed by a sintering process. If the material is powdered metal, the bond may be formed by a melting process. One skilled in the art will appreciate other methods of fusing materials to make a component by additive manufacturing are possible, and the presently disclosed subject matter may be practiced with those methods.

276362B

[0039] In some embodiments, the first material and the second material have different coefficients of thermal expansion. In such embodiments, it may be desirable to configure the plurality of projections 16 to allow some relative movement, thereby reducing the likelihood of failure due to concentrated stresses resulting from thermal growth mismatch.

[0040] Additive manufacturing technology enables the creation of multiple components that are independent entities, but that are created with interlocking features in their construction to limit their range of motion and/or disassembly. In this regard, two or more independent components can be fabricated with interlocking features that effectively form mechanical “roots” that reach across a interlocking transition zone 10, resist disassembly, and have the capacity to carry structural loading across the interlocking transition zone 10. The ability to effectively join two or more components using additive manufacturing technology introduces a wide range of planar or non-planar joints, and can enable the creation of unique assemblies.

[0041] The interlocking material transition zone 10 can provide technical and commercial advantages over the prior art. Joints created using the described method have improved mechanical strength, exhibiting improved shear bonding between regions of different function, composition, or microstructures, and enhanced adhesion at the micro or macro scale. The interlocking material transition zone 10 can also be used, for example, to secure a highly impact resistant protective coating layer to a base material. Bond layer versatility is also improved in that the components may be made of the same or dissimilar material, and the joints may be planar or non-planar. In addition, the interlocking features may be spaced apart to permit a small range of motion between the components, and the joints may have integrated cooling holes or passageways.

[0042] The above-described apparatus and method of joining two or more components using additive manufacturing can be used in a variety of applications and in a variety of industries. For example, components of a gas turbine engine may be constructed using this process. A few examples of components of a gas turbine engine that may be constructed using the above described method are discussed below. However, as one skilled in the art

276362B

will appreciate, these components are only exemplary, and other applications and uses of the described additive manufacturing technology are possible and within the scope of the invention.

[0043] FIG. 8 is a schematic cross-sectional view of a gas turbine engine according to an exemplary embodiment of the present subject matter. More particularly, for the embodiment of FIG. 8, the gas turbine engine is a high-bypass turbofan jet engine 110, referred to herein as “turbofan engine 110.” As shown in FIG. 8, the turbofan engine 110 defines an axial direction A (extending parallel to a longitudinal centerline 112 provided for reference) and a radial direction R. In general, the turbofan 110 includes a fan section 114 and a core turbine engine 116 disposed downstream from the fan section 114.

[0044] The exemplary core turbine engine 116 depicted generally includes a substantially tubular outer casing 118 that defines an annular inlet 120. The outer casing 118 encases, in serial flow relationship, a compressor section including a booster or low pressure (LP) compressor 122 and a high pressure (HP) compressor 124; a combustion section 126; a turbine section including a high pressure (HP) turbine 128 and a low pressure (LP) turbine 130; and a jet exhaust nozzle section 132. A high pressure (HP) shaft or spool 134 drivingly connects the HP turbine 128 to the HP compressor 124. A low pressure (LP) shaft or spool 136 drivingly connects the LP turbine 130 to the LP compressor 122.

[0045] Additionally, for the embodiment depicted, the fan section 114 includes a variable pitch fan 138 having a plurality of fan blades 140 coupled to a disk 142 in a spaced apart manner. As depicted, the fan blades 140 extend outwardly from disk 142 generally along the radial direction R. Each of the plurality of fan blades 140 defines a leading edge 144, or upstream edge, and a tip 146 defined at a radially outer edge of each respective fan blade 140. Each fan blade 140 is also rotatable relative to the disk 142 about a pitch axis P by virtue of the fan blades 140 being operatively coupled to a suitable actuation assembly 148 configured to vary the pitch of the fan blades 140 in a manner described in detail below. The fan blades 140, disk 142, and actuation assembly 148 are together rotatable about the longitudinal axis 112 by LP shaft 136 across a power gear box 150. The power gear box

276362B

150 includes a plurality of gears for stepping down the rotational speed of the LP shaft 136 to a more efficient rotational fan speed. Additionally, for the embodiment depicted, the disk 142 of the variable pitch fan 138 is covered by rotatable front hub 152 aerodynamically contoured to promote an airflow through the plurality of fan blades 140.

[0046] Referring still to the exemplary turbofan engine 110 of FIG. 8, the exemplary fan section 114 additionally includes an annular fan casing or outer nacelle 154 that circumferentially surrounds the fan 138 and/or at least a portion of the core turbine engine 116. It should be appreciated that the nacelle 154 may be configured to be supported relative to the core turbine engine 116 by a plurality of circumferentially-spaced outlet guide vanes 156. Moreover, a downstream section 158 of the nacelle 154 may extend over an outer portion of the core turbine engine 116 so as to define a bypass airflow passage 160 therebetween.

[0047] During operation of the turbofan engine 110, a volume of air 162 enters the turbofan 110 through an associated inlet 164 of the nacelle 154 and/or fan section 114. As the volume of air 162 passes across the fan blades 140, a first portion of the air as indicated by arrows 166 is directed or routed into the bypass airflow passage 160 and a second portion of the air as indicated by arrow 168 is directed or routed into the LP compressor 122. The ratio between the first portion of air 166 and the second portion of air 168 is commonly known as a bypass ratio. The pressure of the second portion of air 168 is then increased as it is routed through the high pressure (HP) compressor 124 and into the combustion section 126, where it is mixed with fuel and burned to provide combustion gases 170.

[0048] The combustion gases 170 are routed through the HP turbine 128 where a portion of thermal and/or kinetic energy from the combustion gases 170 is extracted via sequential stages of HP turbine stator vanes 172 that are coupled to the outer casing 118 and HP turbine rotor blades 174 that are coupled to the HP shaft or spool 134, thus causing the HP shaft or spool 134 to rotate, thereby supporting operation of the HP compressor 124. The combustion gases 170 are then routed through the LP turbine 130 where a second

276362B

portion of thermal and kinetic energy is extracted from the combustion gases 170 via sequential stages of LP turbine stator vanes 176 that are coupled to the outer casing 118 and LP turbine rotor blades 178 that are coupled to the LP shaft or spool 136, thus causing the LP shaft or spool 136 to rotate, thereby supporting operation of the LP compressor 122 and/or rotation of the fan 138.

[0049] The combustion gases 170 are subsequently routed through a jet exhaust nozzle section 182 of the core turbine engine 116 to provide propulsive thrust. Simultaneously, the pressure of the first portion of air 166 is substantially increased as the first portion of air 166 is routed through the bypass airflow passage 160 before it is exhausted from a fan nozzle exhaust section 182 of the turbofan 110 also providing propulsive thrust. The HP turbine 128, the LP turbine 130, and the jet exhaust nozzle section 132 at least partially define a hot gas path 184 for routing the combustion gases 170 through the core turbine engine 116.

[0050] The above-described additive manufacturing technology enables fabrication of complex objects by joining two or more components by an interlocking transition zone 10. This technology may be advantageously employed to manufacture a variety of components in turbofan 110. For example, as discussed below, the additive manufacturing technology can be used to construct a variety of rotor blades 200 exhibiting improved structural integrity and including performance enhancing features such as protective coatings, flexible joints providing a small range of motion, and joints having integrated cooling holes or passageways. One skilled in the art will appreciate that the below-described embodiments are only examples of components that may be fabricated using the above-described additive manufacturing process, and that other similarly constructed components are within the scope of the invention.

[0051] Referring generally to FIGS. 9 through 11, each rotor blade 200 may comprise an airfoil 202, a platform 204, and an integral dovetail 206 used for mounting airfoil 202 to a rotor disk (not shown) in a known manner. The airfoil 202 may extend in a radial direction (R) between a root end 208 located proximate to platform 204 and a tip end 210

276362B

at a distal end of the airfoil 202. Each airfoil 202 includes a first contoured side wall and a second contoured side wall. The first side wall is convex and defines a suction side of airfoil 202, and the second side wall is concave and defines a pressure side of airfoil 202. The side walls are joined at a leading edge 212 and at an axially-spaced trailing edge 214 of airfoil 202. More specifically, airfoil trailing edge 214 is spaced chordwise and downstream from airfoil leading edge 212. First and second side walls extend radially outward in span from blade root 208 positioned adjacent dovetail 206, to an airfoil tip end 210.

[0052] Each rotor blade 200 is typically disposed on a rotor disk (not shown) and placed within a housing. For example, if the rotor blade 200 is configured as a fan blade 140, it may be coupled to a disk 142 such that each blade 140 extends outwardly from disk 142 generally along the radial direction R. The fan 138 and its fan blades 140 may be circumferentially surrounded by an annular fan casing or outer nacelle 154.

[0053] FIGS. 9A and 9B illustrate rotor blades 200, formed using the above-described additive manufacturing technology, and having an airfoil 202 including a protective airfoil tip 216 undetachably coupled to the tip 210 of the airfoil 202. In this manner the airfoil 202 may be protected from damage and wear related to contact with a rotor housing (e.g., shroud) or other objects. In the embodiment shown in FIG. 9A, the plurality of projections 16 in the interlocking transition zone 10 do not permit relative movement between the protective airfoil tip 216 and the airfoil 202. In another embodiment illustrated in FIG. 9B, the plurality of projections 16 may be elongated projections 30. In this regard, the elongated projections 30 may have elongated shafts 32, or may be otherwise fabricated to allow some relative motion between the protective airfoil tip 216 and the airfoil 202. As the rotor blade 200 is rotated about its axis, the elongated projections 30 allow the protective airfoil tip 216 to extend radially from the airfoil 202. In this manner, the protective airfoil tip 216 may follow the profile of the housing more precisely. In addition, the protective airfoil tip 216 may retract when it strikes an object, such as an object entrained in the air flow or the housing itself.

276362B

[0054] FIG. 10 illustrates a rotor blade 200, formed using the above-described additive manufacturing technology, and having an airfoil 202 including a protective leading edge 218 undetachably coupled to a leading edge 212 of the airfoil 202. In this manner, the airfoil 202 may be a base material that is, for example, softer, lighter, and more ductile. This can provide savings in reduced material costs, ease of manufacturing, and reduced fuel consumption. The protective leading edge 218 may be a thermal barrier coating or a bond coat of thermal barrier coating to provide improved thermal durability to the airfoil 202. In other embodiments, the protective leading edge 218 may be a very durable material exhibiting high impact resistance. In this manner, the protective leading edge 218 may protect the airfoil 202 from impact damage and extend its lifetime.

[0055] Platform 204 is typically integral to the rotor blade 200 and is disposed radially between the airfoil 202 and the integral dovetail 206. The platform 204 extends laterally from the rotor blade 200 toward the platforms 204 of adjacent rotor blades 200, such that the plurality of rotor blade platforms 204 form a circumferential flow surface radially disposed at the root 208 of the rotor blades 200. Each platform 204 may define a radially inner surface 220 (e.g., under the platform) and a radially outer surface 222 (e.g., above the platform). As the rotor disk rotates, centrifugal force causes each rotor blade 200 to extend radially from the rotor disk, being held in position by the centripetal force resulting in the integral dovetail 206. High rotational speeds can cause extreme vibration, stresses, and fatigue in the rotor blades 200 and platforms 204. Platform dampers 224 may be disposed on the radially inner surface 220 of the platform 204 to dampen vibrations and force interactions between adjacent rotor blades 200, as well as to seal the space between platforms 204.

[0056] FIG. 11 illustrates a rotor blade 200, formed using the above-described additive manufacturing technology, and having an airfoil 202 including an integral, under-platform damper 224 undetachably coupled to a radially inner surface 220 (e.g., the underside) of an airfoil platform 204. The damper 224 may move relative to the platform 204, such that upon rotation of the rotor disk, centrifugal force may drive the damper 224 radially outward

276362B

to engage the radially inner surface 220 of the platform 204 to which it is connected as well as the radially inner surface 220 of the adjacent platform 204. In this manner, the damper 224 reduces vibrations and unnecessary wear resulting from the vibrations and interactions between rotor blade platforms 204. In some embodiments, the platform 204 may further include a plurality of cooling fluid channels 30 configured to provide fluid communication between the platform 204 and the damper component 224.

[0057] The above described example embodiments of rotor blade 200 applications of the interlocking transition zone 10 and additive manufacturing method are intended only as exemplary embodiments used for the purpose of explanation. The embodiments shown are turbine blades, but could alternatively be compressor blades, fan blades, or any other component that may be constructed using the described method. For example, in the illustrated embodiments of FIGS. 9 through 11, the rotor blades 200 are configured for use in the high pressure turbine 128 or low pressure turbine 130 of gas turbine engine 110, such as turbine rotor blades 174, 178. However, the rotor blades 200 may alternatively be compressor rotor blades configured for use in the low pressure compressor 122 or high pressure compressor 124 of gas turbine engine 110. Similarly, one skilled in the art will appreciate that the rotor blade 200 may be a fan blade, e.g., fan blade 140, mounted within fan section 114 of gas turbine engine 110. These embodiments are not in any way intended to limit the scope of the invention. Indeed, one skilled in the art will appreciate that many other components of gas turbine engine 110 may be constructed using the additive manufacturing technology as described throughout the specification and in the appended figures.

[0058] While there have been described herein what are considered to be preferred and exemplary embodiments of the present invention, other modifications of these embodiments falling within the scope of the invention described herein shall be apparent to those skilled in the art.

WHAT IS CLAIMED IS:

1. A rotor blade, comprising:
an airfoil comprising a plurality of fused layers of a first material formed via additive manufacturing, wherein the airfoil defines a leading edge and a tip at a distal end;
a coupled component comprising a plurality of fused layers of a second material formed via additive manufacturing; and
an interlocking transition zone comprising a plurality of shaft and knob projections alternately extending from the airfoil and the coupled component, respectively, to undetachably couple the airfoil and the coupled component.
2. The rotor blade of claim 1, wherein the coupled component is a protective rotor blade tip, and wherein the interlocking transition zone is disposed at the tip of the airfoil.
3. The rotor blade of claim 2, wherein each of the plurality of shaft and knob projections allows relative motion between the airfoil and the protective rotor blade tip, such that the protective rotor blade tip is retractable when the rotor blade contacts an object.
4. The rotor blade of claim 1, wherein the coupled component is a protective leading edge component, and wherein the interlocking transition zone is disposed at the leading edge of the airfoil.
5. The rotor blade of claim 4, wherein at least a portion of adjacent shaft and knob projections between the airfoil and the protective leading edge component prevent relative motion between the airfoil and the protective leading edge component.
6. The rotor blade of claim 1, wherein the airfoil further defines a platform defining an inner radial boundary for a flow path, and wherein the coupled component is a damper component, and wherein the interlocking transition zone is disposed at an inner surface of the platform.

7. The rotor blade of claim 6, wherein at least a portion of adjacent shaft and knob projections between the platform and the damper component prevent relative motion between the platform and the damper component.

8. The rotor blade of claim 6, wherein each of the plurality of shaft and knob projections allows relative motion between the platform and the damper component, such that the damper component may move in a radial direction relative to the platform.

9. The rotor blade of claim 6, wherein the interlocking transition zone defines a fluid channel, the fluid channel being configured to provide fluid communication between the platform and the damper component.

10. The rotor blade of claim 1, wherein the airfoil comprises a metal alloy, and wherein the coupled component comprises a thermal barrier coating.

11. A method of forming a rotor blade using additive manufacturing, the method comprising:

fusing a plurality of layers of a first material via the additive manufacturing to form an airfoil, wherein the airfoil defines a leading edge and a tip at a distal end;

fusing a plurality of layers of a second material via the additive manufacturing to form a coupled component; and

undetachably coupling the airfoil and the coupled component by forming an interlocking transition zone comprising a plurality of shaft and knob projections alternately extending from the airfoil and the coupled component, respectively.

12. The method of claim 11, wherein the coupled component is a protective rotor blade tip, and wherein the interlocking transition zone is disposed at the tip of the airfoil.

13. The method of claim 12, wherein each of the plurality of shaft and knob projections allows relative motion between the airfoil and the protective rotor blade tip, such that the protective rotor blade tip is retractable when the rotor blade contacts an object.

14. The method of claim 11, wherein the coupled component is a protective leading edge component, and wherein the interlocking transition zone is disposed at the leading edge of the airfoil.

15. The method of claim 14, wherein at least a portion of adjacent shaft and knob projections between the airfoil and the protective leading edge component prevent relative motion between the airfoil and the protective leading edge component.

16. The method of claim 11, wherein the airfoil further defines a platform defining an inner radial boundary for a flow path, and wherein the coupled component is a damper component, and wherein the interlocking transition zone is disposed at an inner surface of the platform.

17. The method of claim 16, wherein at least a portion of adjacent shaft and knob projections between the platform and the damper component prevent relative motion between the platform and the damper component.

18. The method of claim 16, wherein each of the plurality of shaft and knob projections allows relative motion between the platform and the damper component, such that the damper component may move in a radial direction relative to the platform.

19. The method of claim 18, wherein the interlocking transition zone defines a fluid channel, the fluid channel being configured to provide fluid communication between the platform and the damper component.

20. The method of claim 11, wherein the first component and the second component are made of a powdered metal, and fusing is a melting process.
