PHARMACEUTICALLY ACCEPTABLE SALTS OF 3,5-DIAMINOPYRAZOLE KINASE INHIBITORS

CROSS-REFERENCE TO RELATED APPLICATIONS

[0001] This application claims the benefit of priority to U.S. Provisional Patent Application Serial No. 61/879,585, filed September 18, 2013, the disclosure of which is incorporated by reference herein in its entirety.

FIELD

[0002] Provided herein are pharmaceutically acceptable salts of 3,5-diaminopyrazole compounds that are useful for modulating regulated-in-COPD kinase (RC kinase) activity, and pharmaceutical compositions thereof. Also provided herein are methods of their use for treating, preventing, or ameliorating one or more symptoms of a RC kinase-mediated disorder, disease, or condition

BACKGROUND

[0003] Regulated-in-COPD kinase (RC kinase) is closely related to MAPKKK3, which directly regulates the pathways of stress-activated protein kinase (SAPK) and extracellular signal-regulated protein kinase (ERK) by activating SEK and MEK1/2, respectively. *See*, U.S. Pat. No. 7,829,685, the disclosure of which is incorporated herein by reference in its entirety. RC kinase is an upstream activator in MAP kinase signaling cascades, capable of phosphorylating MAP kinase kinases such as MKK4 and MKK6. The activation of MKK4 leads to the phosphorylation of JNK-type MAP kinases, leading to the phosphorylation of c-Jun and thus the activation of the AP-1 transcription factor complex. As a result, interleukin-8 production is increased, leading to the recruitment of inflammatory cells, such as neutrophils. The activation of MKK6 leads to the phosphorylation of p38-type MAP kinases, which is important in the activation of the immune response and key regulators of inflammatory cytokine expression. The occurrence of cellular stresses, the activation of the transcription factor, and the overproduction of interleukin-8 are characteristic of numerous inflammatory diseases. Thus, the regulation of RC kinase activity can potentially be beneficial to patients with inflammatory diseases.

[0004] RC kinase has been shown to be highly expressed in the lung and trachea.

Some of the expressed sequence tags of human RC kinase are also expressed in the lung epithelial cells and in primary lung cystic fibrosis epithelial cells. Microarray analyses of patients with chronic obstructive pulmonary disease (COPD) show that RC kinase is upregulated in the lungs of COPD patients. On cellular level, it has been shown that the expression of RC kinase is upregulated in response to a hyperosmotic or oxidative stress. For example, the expression of RC kinase in cells increase significantly after exposure to potassium chloride or hydrogen peroxide. Potassium chloride subjects cells to a hyperosmotic stress. Hydrogen peroxide subjects cells to an oxidative stress, which impairs the capacity of B cells to stimulate specific T cells. Such upregulation of RC kinase in cells in response to hyperosmotic and oxidative stress suggests that higher expression of RC kinase in lungs of COPD patients may be the result of cellular stresses caused by the irritants in tobacco smoke or stresses caused by inflammatory response to those irritants.

[0005] Therefore, RC kinase inhibitors are potentially useful for the treatment of inflammatory diseases, including COPD.

[00173] The compounds provided herein are intended to encompass all possible stereoisomers, unless a particular stereochemistry is specified. Where the compound provided herein contains an alkenyl or alkenylene group, the compound may exist as one or

mixture of geometric *cis/trans* (or *Z/E*) isomers. Where structural isomers are interconvertible, the compound may exist as a single tautomer or a mixture of tautomers. This can take the form of proton tautomerism in the compound that contains, for example, an imino, keto, or oxime group; or so-called valence tautomerism in the compound that contain an aromatic moiety. It follows that a single compound may exhibit more than one type of isomerism.

[00174] The compounds provided herein may be enantiomerically pure, such as a single enantiomer or a single diastereomer, or be stereoisomeric mixtures, such as a mixture of enantiomers, *e.g.*, a racemic mixture of two enantiomers; or a mixture of two or more diastereomers. As such, one of skill in the art will recognize that administration of a compound in its (*R*) form is equivalent, for compounds that undergo epimerization *in vivo*, to administration of the compound in its (*S*) form. Conventional techniques for the preparation/isolation of individual enantiomers include synthesis from a suitable optically pure precursor, asymmetric synthesis from achiral starting materials, or resolution of an enantiomeric mixture, for example, chiral chromatography, recrystallization, resolution, diastereomeric salt formation, or derivatization into diastereomeric adducts followed by separation.

Methods of Synthesis

[00175] The pharmaceutically acceptable 3,5-diaminopyrazole salts provided herein can be prepared, isolated, or obtained by any method known to one of skill in the art. [00243] Examples of modified release include, but are not limited to, those described in U.S. Pat. Nos.: 3,845,770; 3,916,899; 3,536,809; 3,598,123; 4,008,719; 5,674,533; 5,059,595; 5,591,767; 5,120,548; 5,073,543; 5,639,476; 5,354,556; 5,639,480; 5,733,566; 5,739,108; 5,891,474; 5,922,356; 5,972,891; 5,980,945; 5,993,855; 6,045,830; 6,087,324; 6,113,943; 6,197,350; 6,248,363; 6,264,970; 6,267,981; 6,376,461; 6,419,961; 6,589,548; 6,613,358; and 6,699,500.

[00249] The pharmaceutical compositions provided herein in a modified release dosage form can be prepared by methods known to those skilled in the art, including direct

compression, dry or wet granulation followed by compression, and melt-granulation followed by compression.

2. Osmotic Controlled Release Devices

[00250] The pharmaceutical compositions provided herein in a modified release dosage form can be fabricated using an osmotic controlled release device, including, but not limited to, one-chamber system, two-chamber system, asymmetric membrane technology (AMT), and extruding core system (ECS). In general, such devices have at least two components: (a) a core which contains an active ingredient; and (b) a semipermeable membrane with at least one delivery port, which encapsulates the core. The semipermeable membrane controls the influx of water to the core from an aqueous environment of use so as to cause drug release by extrusion through the delivery port(s).

[00251] In addition to the active ingredient(s), the core of the osmotic device optionally includes an osmotic agent, which creates a driving force for transport of water from the environment of use into the core of the device. One class of osmotic agents is water-swellaable hydrophilic polymers, which are also referred to as “osmopolymers” and “hydrogels.” Suitable water-swellaable hydrophilic polymers as osmotic agents include, but are not limited to, hydrophilic vinyl and acrylic polymers, polysaccharides such as calcium alginate, polyethylene oxide (PEO), polyethylene glycol (PEG), polypropylene glycol (PPG), poly(2-hydroxyethyl methacrylate), poly(acrylic) acid, poly(methacrylic) acid, polyvinylpyrrolidone (PVP), crosslinked PVP, polyvinyl alcohol (PVA), PVA/PVP copolymers, PVA/PVP copolymers with hydrophobic monomers such as methyl methacrylate and vinyl acetate, hydrophilic polyurethanes containing large PEO blocks, sodium croscarmellose, carrageenan, hydroxyethyl cellulose (HEC), hydroxypropyl cellulose (HPC), hydroxypropyl methyl cellulose (HPMC), carboxymethyl cellulose (CMC) and carboxyethyl, cellulose (CEC), sodium alginate, polycarbophil, gelatin, xanthan gum, and sodium starch glycolate.

[00252] The other class of osmotic agents is osmogens, which are capable of imbibing water to affect an osmotic pressure gradient across the barrier of the surrounding coating. Suitable osmogens include, but are not limited to, inorganic salts, such as magnesium sulfate, magnesium chloride, calcium chloride, sodium chloride, lithium chloride, potassium sulfate, potassium phosphates, sodium carbonate, sodium sulfite, lithium sulfate, potassium chloride,

and sodium sulfate; sugars, such as dextrose, fructose, glucose, inositol, lactose, maltose, mannitol, raffinose, sorbitol, sucrose, trehalose, and xylitol; organic acids, such as ascorbic acid, benzoic acid, fumaric acid, citric acid, maleic acid, sebacic acid, sorbic acid, adipic acid, edetic acid, glutamic acid, p-toluenesulfonic acid, succinic acid, and tartaric acid; urea; and mixtures thereof.

[00253] Osmotic agents of different dissolution rates can be employed to influence how rapidly the active ingredient(s) is initially delivered from the dosage form. For example, amorphous sugars, such as MANNOGEM™ EZ (SPI Pharma, Lewes, DE) can be used to provide faster delivery during the first couple of hours to promptly produce the desired therapeutic effect, and gradually and continually release of the remaining amount to maintain the desired level of therapeutic or prophylactic effect over an extended period of time. In this case, the active ingredient(s) is released at such a rate to replace the amount of the active ingredient metabolized and excreted.

[00254] The core can also include a wide variety of other excipients and carriers as described herein to enhance the performance of the dosage form or to promote stability or processing.

[00255] Materials useful in forming the semipermeable membrane include various grades of acrylics, vinyls, ethers, polyamides, polyesters, and cellulosic derivatives that are water-permeable and water-insoluble at physiologically relevant pHs, or are susceptible to being rendered water-insoluble by chemical alteration, such as crosslinking. Examples of suitable polymers useful in forming the coating, include plasticized, unplasticized, and reinforced cellulose acetate (CA), cellulose diacetate, cellulose triacetate, CA propionate, cellulose nitrate, cellulose acetate butyrate (CAB), CA ethyl carbamate, CAP, CA methyl carbamate, CA succinate, cellulose acetate trimellitate (CAT), CA dimethylaminoacetate, CA ethyl carbonate, CA chloroacetate, CA ethyl oxalate, CA methyl sulfonate, CA butyl sulfonate, CA p-toluene sulfonate, agar acetate, amylose triacetate, beta glucan acetate, beta glucan triacetate, acetaldehyde dimethyl acetate, triacetate of locust bean gum, hydroxylated ethylene-vinylacetate, EC, PEG, PPG, PEG/PPG copolymers, PVP, HEC, HPC, CMC, CMEC, HPMC, HPMCP, HPMCAS, HPMCAT, poly(acrylic) acids and esters and poly-(methacrylic) acids and esters and copolymers thereof, starch, dextran, dextrin, chitosan, collagen, gelatin, polyalkenes, polyethers, polysulfones, polyethersulfones, polystyrenes, polyvinyl halides, polyvinyl esters and ethers, natural waxes, and synthetic waxes.

[00256] Semipermeable membrane can also be a hydrophobic microporous membrane, wherein the pores are substantially filled with a gas and are not wetted by the aqueous medium but are permeable to water vapor, as disclosed in U.S. Pat. No. 5,798,119. Such hydrophobic but water-vapor permeable membrane are typically composed of hydrophobic polymers such as polyalkenes, polyethylene, polypropylene, polytetrafluoroethylene, polyacrylic acid derivatives, polyethers, polysulfones, polyethersulfones, polystyrenes, polyvinyl halides, polyvinylidene fluoride, polyvinyl esters and ethers, natural waxes, and synthetic waxes.

[00257] The delivery port(s) on the semipermeable membrane can be formed post-coating by mechanical or laser drilling. Delivery port(s) can also be formed in situ by erosion of a plug of water-soluble material or by rupture of a thinner portion of the membrane over an indentation in the core. In addition, delivery ports can be formed during coating process, as in the case of asymmetric membrane coatings of the type disclosed in U.S. Pat. Nos. 5,612,059 and 5,698,220.

[00258] The total amount of the active ingredient(s) released and the release rate can substantially be modulated *via* the thickness and porosity of the semipermeable membrane, the composition of the core, and the number, size, and position of the delivery ports.

[00259] The pharmaceutical compositions in an osmotic controlled-release dosage form can further comprise additional conventional excipients or carriers as described herein to promote performance or processing of the formulation.

[00260] The osmotic controlled-release dosage forms can be prepared according to conventional methods and techniques known to those skilled in the art (*see, Remington: The Science and Practice of Pharmacy*, supra; Santus and Baker, *J. Such multiparticulates can be made by the processes known to those skilled in the art, including wet-and dry-granulation, extrusion/spheronization, roller-compaction, melt-congealing, and by spray-coating seed cores. *See, for example, Multiparticulate Oral Drug Delivery*; Marcel Dekker: 1994; and *Pharmaceutical Pelletization Technology*; Marcel Dekker: 1989.

[00264] Other excipients or carriers as described herein can be blended with the pharmaceutical compositions to aid in processing and forming the multiparticulates. The resulting particles can themselves constitute the multiparticulate device or can be coated by various film-forming materials, such as enteric polymers, water-swellaable, and water-soluble polymers. The multiparticulates can be further processed as a capsule or a tablet.

Example 1

Preparation of a 3,5-diaminopyrazole salt

[00301] A stirring solution of a free base 3,5-diaminopyrazole compound (2 mL, 100 mg/mL) in 1,4-dioxane was treated with a solution of an acid (8.0 eq., 1.0 N) in 1,4-dioxane.

The reaction mixture was heated at 60 °C and stirred for 1 hr, and then allowed to stir at room temperature overnight. If precipitate was formed, the suspension was filtered, and the residue was washed with diethyl ether to obtain the salt product. If no precipitate had formed, 2 mL of diethyl ether was added to the reaction mixture, and the resulting solids were isolated by suction filtration. The obtained product was characterized by melting point. If salt formation was not successful in 1,4-dioxane for a certain counter-ion, the above procedures were repeated using either ethanol or DMF as the solvent for salt formation. The exemplary salts provided herein are comprised of a 1:1 ratio of freebase to acid, as confirmed by NMR spectroscopy.

[00323] Solubility assessment: A preweighed amount of powder of a salt was treated with water to target a nominal concentration of 10 mg/mL. If a clear solution was obtained, then the solubility was noted as ≥ 10 mg/mL. If a suspension was obtained, additional water was added to target a nominal concentration of 5 mg/mL. If still a suspension after the addition of water, additional water was added to target a lower nominal concentration. If a suspension was still observed at a nominal concentration of 0.1 mg/mL, the suspension was filtered through a 0.4 micron filter, and the filtrate was analyzed by RP-HPLC to ascertain the solubility range of the salt. The solubilities of the salts described herein in water are summarized in Table 1.

[00324] Melting point analysis: A sample a salt was placed in a microcapillary tube. Melting point ranges were determined on a Optimelt (Stanford Research Systems) Melting point apparatus. The melting point ranges of various salts are summarized in Table 2.

Enzymatic Assays for Kinase Inhibitory Activity

[00325] Solutions of a test compound, Crebtide (a substrate), a kinase, and ATP were prepared using 1x MAPK Buffer (50 mM HEPES, 1 mM EGTA, 10 mM EGTA, 10 mM MgCl_2 , 2 mM DTT, and 0.01% Tween 20). The test compound solution had a concentration of either 10 μM or 10 x IC_{50} of the compound. The Crebtide solution had a concentration of 200 nM. The kinase domain protein of RC kinase had a concentration of 3 mg/mL. The full-length kinase protein of RC kinase had a concentration of 40 mg/mL. ATP had a concentration of 4 μM when the kinase domain protein was used or 12 μM when the full-length protein was used in the assay.

[00326] To each well, the test compound (1 μL) was first added (in duplicate) to reach a final concentration of 1 μM or 1 x IC_{50} of the compound. The kinase (5 μL) was then added to each well to reach a final concentration of 1 mg/mL for the kinase domain or 20 mg/mL for the full-length domain. Each plate included a positive and negative controls in duplicate wells. Crebtide (2.5 μL) was then added to each well in duplicate to reach a final concentration of 50 nM. If the full-length kinase was used, the plates were incubated for 45 min at room temperature before proceeding further. ATP (2.5 μL) was added to each well to reach a final concentration of 1 μM for the kinase domain and 3 μM for the full-length.

[00327] After the addition of ATP, the plates were incubated for 45 min at room temperature. During the incubation, an EDTA solution (40 mM) and anti-Crebtide (16 mM) were prepared. Additionally, a detection buffer stock solution was diluted ten fold before use.

[00328] After the incubation, the anti-Crebtide (5 μL) and EDTA (5 μL) were added to each well to reach their final concentrations of 4 mM and 10 mM, respectively. The plates were allowed to develop at room temperature for 45 min. The plates were then read at 665 nm and 615 nm using Perkin Elmer Lance machine.

[00329] The biological results of inhibition of the kinase domain protein of RC kinase by selected free base compounds are summarized in Table 3, wherein A represents at least 50% inhibition of the RC kinase activity at 1 μM ; B represents no greater than 50% but at

least 20% inhibition of the RC kinase activity at 1 μ M; C represents no greater than 20% but at least 5% inhibition of the RC kinase activity at 1 μ M; and D represents no greater than 5% inhibition of the RC kinase activity at 1 μ M. As will be appreciated by those skilled in the art, the activity of a particular salt provided herein will be the same as the activity for the parent free-base compound.
