Cross-Reference

This application claims priority to Swiss Patent Application No. 00025/21 filed January 13, 2021, Swiss Patent Application No. 00386/21 filed April 14, 2021, Swiss Patent Application No. 00655/21 filed June 4, 2021, and U.S. Provisional Application No. 63/281,049 filed November 18, 2021, the contents of each of which are incorporated herein by reference in their entireties.

Field of disclosure

The present disclosure relates to new compounds as modulators of cereblon. The disclosure also relates to methods of preparation of these compounds, compositions comprising these compounds, and methods of using them in the treatment of abnormal cell growth in mammals, especially humans.

Background

The ubiquitin proteasome system can be manipulated with different small molecules to trigger targeted degradation of specific proteins of interest. Promoting the targeted degradation of pathogenic proteins using small molecule degraders is emerging as a new modality in the treatment of diseases. One such modality relies on redirecting the activity of E3 ligases such as cereblon (a phenomenon known as E3 reprogramming) using low molecular weight compounds, which have been termed molecular glues to promote the poly-ubiquitination and ultimately proteasomal degradation of new protein substrates involved in the development of diseases. The molecular glues bind to both the E3 ligase and the target protein, thereby mediating an alteration of the ligase surface and enabling an interaction with the target protein. Particularly relevant compounds for the E3 ligase cereblon are the IMiD (immunomodulatory imide drugs) class including Thalidomide, Lenalidomide and Pomalidomide. These IMiDs have been approved by the FDA for use in hematological cancers. However, compounds for efficiently targeting other diseases, in particular other types of cancers, are still required.

Summary of disclosure

It is therefore an object of the present disclosure to advance the state of the art of cereblon modulators and provide modulators for novel use in different diseases, in particular in different cancers.

In some embodiments, compounds are provided for use in therapy of solid tumors, such as for use in the therapy of lung cancer for example, non-small cell lung cancer (e.g., squamous cell lung cancer) and small cell lung cancer, breast cancer, and neuroendocrine cancer, e.g., neuroendocrine prostate cancer such as castration-resistant neuroendocrine prostate cancer (NEPC) and lung neuroendocrine tumors (Lu-NETs). In some embodiments, compounds are provided for use in therapy of blood-borne (or haematological) cancers such as for use in the therapy of leukemias (e.g. acute myelogenous leukemia (AML)) and myelomas (e.g. multiple myeloma (MM)).

The present disclosure is in a first aspect directed towards a compound or pharmaceutically acceptable salts or stereoisomers thereof of formula I:

Brief description of the figures

Figure 1: Figure 1A shows that cells treated with 0.3 μM compound 10 induces complete degradation of GSPT1, while no induction of degradation of IKZF1, IKZF3, SALL4, CK1alpha was observed at concentrations up to 30 μM. Figure 1B shows that based on a mass spectrometry-based proteomics analysis of a cancer cell line treated with compound 10, GSPT1 was the most statistically significant downregulated protein (x-axys represents the protein fold-change (log_2); y-axis represents the p-value, which is an assessment of whether the observation is a result of change or the result of a random occurrence, with smaller p-values suggesting stronger evidence of an actual change).

Figure 2: Figure 2A shows that NSCLC cell lines expressing high levels of N-Myc (NCI-H1155 represented as filled triangles, ABC-1 represented as filled rhombi) were highly sensitive to treatment with compound 10, when compared to the cell lines expressing low levels of N-Myc (EBC-1 represented as empty triangles, NCI-H2023 represented as empty circles). GSPT1 was degraded by compound 10 after six hours of treatment in high N-Myc NCI-H1155 and ABC-1 cells with a DC50 of 3 nM and 22 nM, respectively (x-axys represents μM concentration of compound 10; y-axis represents the viability in %). In both cell lines, we observed complete degradation of GSPT1, Figure 2B illustrates that compound 10 degrades GSPT1 in a concentration dependent manner (x-axys represents μM concentration of compound 10; y-axis represents relative levels of GSPT1)

Figure 3: Figure 3A shows that oral administration of compound 10 in a N-Myc-driven mouse xenograft model using the human cell line NCI-H1155 led to tumor growth inhibition (with no body weight loss observed). At a dose of 1 mg/ kg once daily, tumor growth was suppressed for two weeks. At a dose of 3 mg/kg once daily or 6 mg/kg dosed for five days on and nine days off, tumor size decreased, became undetectable by day eight and remained so until the end of the study at day 21 (x-axys represents days post treatment initiation [days]; y-axis represents tumor volume [mm^3], mean ±SEM; empty circles O: vehicle, PO, QD; filled squares, 1 mg/kg, PO, QD; filled triangles, 3 mg/kg PO, QD; filled triangles inverted, 6 mg/kg, PO, 5 on – 9 off; filled rhombi, gemcitabine 40 mg/kg IP, Q4Dx5).

Figure 3B shows complete degradation of GSPT1 in tumors of mice treated with compound 10 at all three dose levels as compared to mice treated with vehicle control (from left to right: vehicle, 1 mg/kg, 3 mg/kg, 6 mg/kg).

Figures 3C and 3D show that oral administration of compound 10 in a N-Myc-driven mouse xenograft model using the human cell line NCI-H1770 and NCI-H526, respectively, led to tumor growth inhibition (with no body weight loss observed). At a dose of 3 mg/kg once daily or 6 mg/kg dosed for five days on and nine days off, tumor size decreased and remained so until the end of the study (x-axys represents days post treatment initiation [days]; y-axis represents tumor volume [mm^3], mean ±SEM; empty circle O: vehicle, PO, QD; filled triangles, 3 mg/kg PO, QD; filled triangles inverted, 6 mg/kg, PO, 5 on – 9 off; filled rhombi, cisplatine 6 mg/kg IP, QWx3).

In the solid state, it may exist in, or as a mixture thereof. In crystalline solvates, solvent molecules are incorporated into the crystalline lattice during crystallization. The formation of solvates may include non-aqueous solvents such as, but not limited to, ethanol, isopropanol, DMSO, acetic acid, ethanolamine, or ethyl acetate, or aqueous solvents such as water (also called "hydrates"). Different polymorphs may be produced, for example, by changing or adjusting the reaction conditions or reagents.

In a further aspect, the disclosure also provides methods of preparation of the compounds of formula I-VIII of the disclosure. In some embodiments, they are prepared according to the general procedure A.

In yet another aspect, the disclosure further provides a pharmaceutical composition comprising a therapeutically-effective amount of one or more of the compounds of the disclosure or pharmaceutically acceptable salt thereof and one or more pharmaceutically acceptable carriers and/or excipients (also referred to as diluents). The excipients are acceptable in the sense of being compatible with the other ingredients of the formulation and not deleterious to the recipient thereof (i.e., the patient). The term "therapeutically-effective amount", or "therapeutically effective amount" as used herein refers to the amount of a compound (as such or in form of a pharmaceutical composition) of the present disclosure which is effective for producing some desired therapeutic effect.

Pharmaceutical compositions may be in unit dose form containing a predetermined amount of a compound of the disclosure per unit dose. Such a unit may contain a therapeutically effective dose of a compound of the disclosure or salt thereof or a fraction of a therapeutically effective dose such that multiple unit dosage forms might be administered at a given time to achieve the desired therapeutically effective dose. Preferred unit dosage formulations are those containing a daily dose or sub-dose, or an appropriate fraction thereof, of a compound of the disclosure or salt thereof.

The compounds of the disclosure may be administered by any acceptable means in solid or liquid form, including (1) oral administration, for example, drenches (aqueous or non-aqueous solutions or suspensions), tablets, e.g., those targeted for buccal, sublingual, and systemic absorption, boluses, powders, granules, pastes for application to the tongue; (2) parenteral administration, for example, by subcutaneous, intramuscular, intravenous or epidural injection as, for example, a sterile solution or suspension, or sustained-release formulation; (3) topical application, for example, as a cream, ointment, or a controlled-release patch or spray applied to the skin; (4) intravaginally or intrarectally, for example, as a pessary, cream or foam; (5) sublingually; (6) ocularly; (7) transdermally; (8) nasally; (9) pulmonary; or (10) intrathecally.

In the case of capsules, tablets and pills, the pharmaceutical compositions may also comprise buffering agents. Solid compositions of a similar type may also be employed as fillers in soft and hard-shelled gelatin capsules using such excipients as lactose or milk sugars, as well as high molecular weight polyethylene glycols and the like. A tablet may be made by compression or molding, optionally with one or more accessory ingredients. Compressed tablets may be prepared using binder (for example, gelatin or hydroxypropylmethyl cellulose), lubricant, inert diluent, preservative, disintegrant (for example, sodium starch glycolate or cross-linked sodium carboxymethyl cellulose), surface-active or dispersing agent. Molded tablets may be made by molding in a suitable machine a mixture of the powdered compound moistened with an inert liquid diluent. The tablets, and other solid dosage forms of the pharmaceutical compositions of the present disclosure, such as dragees, capsules, pills and granules, may optionally be scored or prepared with coatings and shells, such as enteric coatings and other coatings well known in the pharmaceutical-formulating art. They may also be formulated so as to provide slow or controlled release of the active ingredient therein using, for example, hydroxypropylmethyl cellulose in varying proportions to provide the desired release profile, other polymer matrices, liposomes and/or microspheres. They may be formulated for rapid release, e.g., freeze-dried. They may be sterilized by, for example, filtration through a bacteria-retaining filter, or by incorporating sterilizing agents in the form of sterile solid compositions which can be dissolved in sterile water, or some other sterile injectable medium immediately before use. These compositions may also optionally contain opacifying agents and may be of a composition that they release the active ingredient(s) only, or preferentially, in a certain portion of the gastrointestinal tract, optionally, in a delayed manner. Examples of embedding compositions which can be used include polymeric substances and waxes. The active ingredient can also be in micro-encapsulated form, if appropriate, with one or more of the above-described excipients.

Liquid dosage forms for oral administration of the compounds of the disclosure include pharmaceutically acceptable emulsions, microemulsions, solutions, suspensions, syrups and elixirs. In addition to the active ingredient, the liquid dosage forms may contain inert diluents

commonly used in the art, such as, for example, water or other solvents, solubilizing agents and emulsifiers, such as ethyl alcohol, isopropyl alcohol, ethyl carbonate, ethyl acetate, benzyl alcohol, benzyl benzoate, propylene glycol, 1,3-butylene glycol, oils (in particular, cottonseed, groundnut, corn, germ, olive, castor and sesame oils), glycerol, tetrahydrofuryl alcohol, polyethylene glycols and fatty acid esters of sorbitan, and mixtures thereof. An oral composition can also include adjuvants such as wetting agents, emulsifying and suspending agents, sweetening, flavoring, coloring, perfuming and preservative agents.

In form of suspensions, a compound may contain suspending agents as, for example, ethoxylated isostearyl alcohols, polyoxyethylene sorbitol and sorbitan esters, microcrystalline cellulose, aluminum metahydroxide, bentonite, agar-agar and tragacanth, and mixtures thereof.

Dosage forms for rectal or vaginal administration of a compound of the disclosure include a suppository, which may be prepared by mixing one or more compounds of the disclosure with one or more suitable nonirritating excipients or carriers comprising, for example, cocoa butter, polyethylene glycol, a suppository wax or a salicylate, and which is solid at room temperature, but liquid at body temperature and, therefore, will melt in the rectum or vaginal cavity and release the active compound. Other suitable forms include pessaries, tampons, creams, gels, pastes, foams or spray formulations containing such carriers as are known in the art to be appropriate.

Dosage forms for the topical or transdermal administration of a compound of the disclosure include powders, sprays, ointments, pastes, creams, lotions, gels, solutions, patches and inhalants. The active compound may be mixed under sterile conditions with a pharmaceutically-acceptable carrier, and with any preservatives, buffers, or propellants which may be required. Such ointments, pastes, creams and gels may contain, in addition to a compound of the disclosure, excipients, such as animal and vegetable fats, oils, waxes, paraffins, starch, tragacanth, cellulose derivatives, polyethylene glycols, silicones, bentonites, silicic acid, talc and zinc oxide, or mixtures thereof.

Dosage forms such as powders and sprays for administration of a compound of the disclosure, may contain excipients such as lactose, talc, silicic acid, aluminum hydroxide, calcium silicates and polyamide powder, or mixtures of these substances. Sprays can additionally contain customary propellants, such as chlorofluorohydrocarbons and volatile unsubstituted hydrocarbons, such as butane and propane.

Dosage forms such as transdermal patches for administration of a compound of the disclosure may include absorption enhancers or retarders to increase or decrease the flux of the compound across the skin. The rate of such flux can be controlled by either providing a rate controlling membrane or dispersing the compound in a polymer matrix or gel. Other dosage forms contemplated include ophthalmic formulations, eye ointments, powders, solutions and the like. It is understood that all contemplated compositions must be stable under the conditions of manufacture and storage, and preserved against the contaminating action of microorganisms, such as bacteria and fungi.

The dosage levels of a compound of the disclosure in the pharmaceutical compositions of the disclosure may be adjusted in order to obtain an amount of a compound of the disclosure which is effective to achieve the desired therapeutic response for a particular patient, composition, and mode of administration, without being deleterious to the patient. The dosage of choice will depend upon a variety of factors including the nature of the particular compound of the present disclosure used, the route of administration, the time of administration, the rate of excretion or metabolism of the particular compound used, the rate and extent of absorption, the duration of the treatment, other drugs, compounds and/or materials used in combination with the particular compound, the age, sex, weight, condition, general health and prior medical history of the patient being treated, and like factors well known in the medical arts. A medical practitioner having ordinary skill in the art can readily determine and prescribe the effective amount of the pharmaceutical composition required.

Typically, a suitable daily dose of a compound of the disclosure will be that amount of the compound, which is the lowest dose effective to produce a therapeutic effect. Such an effective dose will generally depend upon the factors described above. Generally, oral, intravenous, intracerebroventricular and subcutaneous doses of the compounds of this disclosure for a patient, when used for the indicated analgesic effects, will range from about 0.0001 to about 100 mg, more usual 0.1 to 100 mg/kg per kilogram of body weight of recipient (patient, mammal) per day. Acceptable daily dosages may be from about 1 to about 1000 mg/day, and for example, from about 1 to about 100 mg/day.

A compound of the disclosure, or a pharmaceutically acceptable salt, or stereoisomer, thereof, may be administered once daily (QD) or divided into multiple daily doses such as twice daily (BID), three times daily (TID), and four times daily (QID) or may be administered in regular intervals of more than one day, such as every two days (Q2D). Administration may

be continuous (i.e., daily for consecutive days or every day) or intermittent, e.g., in cycles (i.e., including days, weeks, or months of rest without drug). In some embodiments, a compound of the disclosure, or a pharmaceutically acceptable salt, or stereoisomer thereof, is administered every day for at least 21 days. In some embodiments, a compound of the disclosure, or a pharmaceutically acceptable salt or stereoisomer thereof, is administered every two days for at least 21 days.

The term "intermittent" or "intermittently" as used herein is intended to mean stopping and starting at either regular or irregular intervals. For example, intermittent administration of a compound of the disclosure, or a pharmaceutically acceptable salt, or stereoisomer, thereof, is administration for one to six days per week, administration in cycles (e.g., daily administration for two to eight consecutive weeks, then a rest (or holiday) period with no administration for up to one week), or administration on alternate days. The term "cycling" as used herein is intended to mean that a compound of the disclosure, or a pharmaceutically acceptable salt, or stereoisomer, thereof, is administered daily or continuously but with a rest period. In some embodiments, the rest period is the same length as the treatment period. In other embodiments, the rest period has different length from the treatment period. In some embodiments, a compound of the disclosure, or a pharmaceutically acceptable salt, or stereoisomer, thereof, is administered intermittently once per day for 5 days followed by a rest of 3 days (i.e. 5 days on/3 days off). This intermittent administration is repeated for 3 to 4 cycles. In some embodiments, a compound of the disclosure, or a pharmaceutically acceptable salt, or stereoisomer thereof, is administered intermittently once per day for 5 days followed by a rest of 9 days (i.e. 5 days on/9 days off). This intermittent administration is repeated for 2 cycles. It is understood that dosing regimen also depend on factors as indicated above, e.g. on the administration, and can be readily arrived at by one skilled in medicine or the pharmacy art.

The compounds of the disclosure modulate the activity of cereblon. Thus, the compounds and compositions of the disclosure can be useful as a medicament, i.e. as a medicament in therapy, more specifically for the treatment of cancer, as detailed below. Therefore, in a further aspect, the present disclosure provides a method of treatment of a mammal, for example, a human, suffering from cancer, as detailed below. The term "treatment" is intended to encompass prophylaxis, therapy and cure. Examples

The compounds provided herein can be prepared from readily available starting materials using the following general methods and procedures. It will be appreciated that where typical or preferred process conditions (*i.e.*, reaction temperatures, times, mole ratios of reactants, solvents, pressures, *etc.*) are given, other process conditions can also be used unless otherwise stated. Optimum reaction conditions may vary with the particular reactants or solvent used, but such conditions can be determined by one skilled in the art by routine optimization.

Example 3: Compound activity by Fluorescent Polarization assay

Compound activity was monitored in a fluorescence polarization (FP) homogeneous assay using 1-[5-({2-[2-(2-{[2-(2,6-dioxopiperidin-3-yl)-1,3-dioxo-2,3-dihydro-1H-isoindol-4-yl]oxy}acetamido)ethoxy]ethyl}carbamoyl)pentyl]-3,3-dimethyl-2-[(1E,3E)-5-[(2E)-1,3,3-trimethyl-5-sulfo-2,3-dihydro-1H-indol-2-ylidene]penta-1,3-dien-1-yl]-3H-indol-1-ium-5-sulfonate as a fluorescent probe. Unless otherwise stated, all reagents were purchased from Sigma Aldrich. Enzymatic reactions were conducted in Perkin-Elmer Black 384 well ProxiPlate Plus (catalogue no. 6008269) in 10 µL total volume. Full length wild-type cereblon CRBN (80.0 nM, 10 µL) was incubated in assay buffer containing 20 mM HEPES (pH 8.0), 150 NaCl, 0.5 mM TCEP and 0.05% Tween 20 in the presence or absence of compound (300 nL). Inhibitors were stored as 10 mM DMSO stocks in an inert environment (low humidity, dark, low oxygen, room temperature) using the Storage Pod System. Compounds and DMSO were dispensed using the Echo E5XX (Labcyte Inc. USA) to give concentrations from 300 to 0.937 or 3000 to 9.3 nM in a 12 data point curve. Mutant YWAA CRBN (80.0 nM, 10 µL) which does not interact with the fluorescent probe was used as a negative control for the assay. Following incubation at room temperature for 30 min, the assay was initiated by dispensing the probe to a final concentration of 5 nM (2.5 nL of a 20 µM stock) using the Echo E5XX. FP was measured after a period of 12 hours using a Pherastar plate reader (BMG Labtech, Germany) exciting at 590 nm and measuring the amount of parallel and perpendicular light at 675 nm. The FP signal was subsequently normalized to the no-compound control (i.e., DMSO). Analysis and IC50 values were derived using Dotmatics (Dotmatics UK) software.

Table 2: IC50 values determined in the fluorescence polarization assay indicating the cereblon binding

Table 2 assigns each compound a code indicating the ability for cereblon binding by measn of their IC50 values: A, B, C or D. According to the code, A represents an IC50 value of ≤500 nM, B represents an IC50 value >500 nM and ≤1100 nM, C represents an IC50 value of >1100 nM and ≤1700 nM and D represents an IC50 value of >1700 nM.

Example 4: Compound binding by Immunofluorescence assay

The representative compounds were tested in an immunofluorescence assay for their activity to bind to degrade GSPT1. CAL-51 cells were purchased from DSMZ (cat. Number ACC302), sub-cultured in 90% Dulbecco's MEM (4.5 g/L glucose, Gibco 11965) + 10% heat inactivated FBS (BioConcept, 2-01F136I) and incubated at 37 °C, 5% CO_2. For the assay, imaging microtiterplate Cell Carrier 96 Ultra (Perkin Elmer 6055302) were pre-coated with Fibronectin (Sigma F085, 30µl at 0.2µg/ml) in PBS (100µl, Gibco 14190) for 45 min at room temperature, rinsed with PBS and CAL-51 cells (30K cells/well) were plated and let to adhere overnight. Cells were treated with compounds typically using a serial dilution ranging from 30 µM to 0.1 nM for 6 hours. Compounds were stored at 10 mM DMSO stocks. Vehicle (DMSO), positive (CC-885, 10 µM) and rescue controls (positive control plus 0.2 µM bortezomib) were also included atthis stage. Cells were subsequently rinsed with PBS and fixed in 10% Formalin solution (50µl, Sigma HT5011)) for 20 mins at room temperature. Following three consecutive PBS washes (100µl), cells were permeabilized in 0.1% Triton X-100 in PBS (Sigma 93443, 50µl) for 15 mins at room temperature. Following three further PBS washes, 50µl blocking buffer (1% BSA, Sigma A4503, in PBS) was added for 45 min for signal-to-noise reduction.

Primary antibody (human GSPT1, Sigma HPA052488) was diluted in blocking buffer (dil.1/300, 35µl/well) and incubated with the cells overnight at 4°C. After three PBS washes, Alexa-fluor 488 coupled secondary antibodies (Invitrogen, A32731, dil.1/1000), Alexa-fluor 647-Phalloïdin (Invitrogen, A22287, dil.1/200) and DAPI (Thermo,

#62248, dil.1/1000) were diluted in blocking buffer and incubated with the samples for 2 hours at room temperature. After three final PBS washes, samples were conserved in 100µl PBS in the dark, until measurement. Image acquisition was performed on the Operetta High-Content Imager (Perkin-Elmer). Fluorescence intensity of Alexa-Fluor 488 (GSPT1), Alexa-Fluor 647 (Actin) and DAPI (Nucleus) were measured. For the determination of GSPT1 DC_{50} values, a custom algorithm implemented in the PerkinElmer image analysis software Harmony-Acapella® was developed. After user-defined setting of adjustment parameters, the analysis was run identically without human intervention for all image fields. DAPI staining of the nuclei was used to determine the location of cells using standard nuclei detection modules. Segmentation artifacts were removed by threshold-based filters for area, roundness and intensity. The outline of the cells was determined analogously from the sum of the normalized, smoothed DAPI and Actin channel, starting from each nucleus. The Alexa-Fluor 488 (GSPT1) signal intensity in each cell was finally measured, in order to obtain a Mean intensity per cell. GSPT1 degradation (DC_{50}) was calculated after normalization to controls and data import in CDD vault Database, using non-linear regression.

Example 5: CK1alpha/Ikaros/Aiolos/ZFP91 Selectivity determination by Western blot assay

MM1S cells were purchased from ATCC (cat. Number CRL-2974), sub-cultured in 90% RPMI 1640 with 10% FBS, supplemented with 1x P/S and incubated at 37°C, 5% CO2. Compounds were stored as 10 mM DMSO stock. For the assay, MM1S cells (3 million cells/well) were plated in 6-well plates and incubated over night. Cells were treated with respective compounds using a serial dilution: 0.3 µM, 3 µM and 30 µM as well as a vehicle only (DMSO) control for 6 hours. Media with suspension cells was subsequently transferred to 15 mL conical tubes, wells rinsed twice with ice-cold PBS and merged with cell suspension in respective 15 mL conical tube. Cells were spinned down, supernatant aspirated, pellets resuspended in ice-cold PBS and transferred to microtubes. Cells were spinned down, supernatant aspirated and pellets resuspended in 120 µL RIPA lysis buffer supplemented with protease and phosphatase inhibitors. Cell lysates were incubated on ice for 20 minutes followed by centrifugation at >20,000xg for 5 min. Supernatants were transferred to fresh microtubes and stored at -80°C. Total protein concentration was determined using a BCA assay with a BSA standard curve and concentration of all samples was adjusted to 1 mg/mL. 25 µL 4x LDS sample buffer supplemented with 100 mM DTT was added to 75 µL sample. Samples were centrifuged (8,000xg, 1 min) and incubated at 95°C for 5 min followed by another centrifugation step (8,000xg, 1 min). 20 µL of each sample was loaded on a 4-12% gel alongside a protein molecular weight marker. Gels were run in the presence of MOPS

buffer at 80 Volts for 30 min, followed by 120 Volts for 1.5 h and proteins subsequently transferred onto nitrocellulose membranes at 20 Volts for 7 min using an iBlot2 Gel Transfer Device. Membranes were then cut horizontally into two pieces, covering 80 – 50 kDa and 50 – 25 kDa. Blocking the membranes was performed by gently shaking in 5% (w/v) skim milk in TSB-T for 1hr at room temperature. All primary antibodies were used at a 1/1000 in 5% (w/v) BSA dissolved in TBST and incubated with membranes over night at 4°C. Anti-IKZF1 (Ikaros; D6N9Y; 14859S), anti-IKZF3 (Aiolos; D1C1E; 15103S) antibodies were purchased from Cell Signalling Technology, anti-ZFP91 antibody from Bethyl laboratories, anti-GSPT1 from Sigma Aldrich (HPA052488) and anti CK1alpha from AbCam (ab206652). After three washes with 1x TBST for 5 min, HRP-coupled secondary antibodies diluted in 5% (w/v) BSA/TBST (Goat Anti-Rb IgG, dil. 1/10,000; Goat Anti-Mouse IgG, dil. 1/5000) were added for 1hr at room temperature. After three washes with 1x TBST (5 minutes each), membranes were incubated with ECL reagent for 1 min at room temperature. Chemiluminescence signals were then detected using a LAS-4000 system with default settings and signals quantified using Image Studio Lite software (version 5.2). Membrane parts previously incubated with antibody against CK1alpha were stripped off antibodies by incubating with stripping buffer for 30 minutes followed by three washed with TBST (5 min each), blocking with 5% (w/v) skim milk for 1hr, and incubation with primary antibody against GAPDH overnight at 4°C. Subsequent washes, incubation with secondary antibody and signal acquisition were performed as described above.

Quantitative Proteomics Analysis*:* ABC1 cells were treated with either DMSO (2 replicates) or compound 10 at 100nM (2 replicates) for 6hr. Proteins were extracted with the PreOmics iST-NHS lysis buffer (#P.O.00030). The samples were then processed using the PreOmics kit following their recommended protocol with minor modifications. In brief, the proteins were reduced, alkylated and digested for 2h at 37 °C. The peptides were then labelled with TMT reagent (1:4; peptide:TMT label) (Thermo Fisher Scientific). After quenching, the peptides were purified, and the 16 samples were combined to a 1:1 ratio. Mixed and labeled peptides were subjected to high-pH reversed-phase HPLC fractionation on an Agilent X-bridge C18 column (2.1 mm ID, 3.5 µm particles and 15 cm in length). Using an Agilent 1260 Infinity II LC system, a 60 min linear gradient from 0 % to 45 % 10 mM ammonium formate in 90% acetonitrile separated the peptide mixture into a total of 60 fractions, which were then consolidated into 24 fractions. The dried 24 fractions were reconstituted in 0.1 % formic acid for LC-MS3 analysis. Labelled peptides were loaded onto an Aurora column from Ionopticks

(75 µm ID, 1.6 µm particles, 25 cm in length) in an EASY-nLC 1200 system. The peptides were separated using a 168 min gradient from 4 % to 30 % buffer B (80 % acetonitrile in 0.1% formic acid) equilibrated with buffer A (0.1 % formic acid) at a flow rate of 400 nl/min. Eluted TMT peptides were analyzed on an Orbitrap Eclipse mass spectrometer (Thermo Fisher Scientific). MS1 scans were acquired at resolution 120,000 with 400-1400 m/z scan range, AGC target $4x10^5$, maximum injection time 50 ms. Then, MS2 precursors were isolated using the quadrupole (0.7 m/z window) with AGC $1x10^4$ and maximum injection time 50 ms. Precursors were fragmented by CID at a normalized collision energy (NCE) of 35 % and analyzed in the ion trap. Following MS2, synchronous precursor selection (SPS) MS3 scans were collected by using high energy collision-induced dissociation (HCD) and fragments were analyzed using the Orbitrap (NCE 55 %, AGC target $1x10^5$, maximum injection time 120 ms, resolution 60,000). Protein identification and quantification were performed using Proteome Discoverer 2.4.0.305 with the SEQUEST algorithm and Uniprot human database (2021-01-29, 20614 protein sequences). Mass tolerance was set at 10 ppm for precursors and at 0.6 Da for fragment. Maximum of 3 missed cleavages were allowed. Methionine oxidation was set as dynamic modification, while TMT tags on peptide N termini/lysine residues and cysteine alkylation (+113.084) were set as static modifications. The list of identified peptide spectrum matches (PSMs) was filtered to respect a 1% False Discovery Rate (FDR) after excluding PSMs with TMT reporter ion signal-to-noise value lower than 10 and a precursor interference level value higher than 50%. Subsequently, protein identifications were inferred from protein specific peptides, i.e. peptides matching multiple protein entries were excluded. Protein relative quantification was performed using an in-house developed java notebook. This analysis included multiple steps; adjustment of reporter ion intensities for isotopic impurities according to the manufacturer's instructions, global data normalization by equalizing the total reporter ion intensity across all channels, summation of reporter ion intensities per protein and channel, calculation of protein abundance log2 fold changes (L2FC) and testing for differential abundance using moderated t-statistics where the resulting p-values reflect the probability of detecting a given L2FC across sample conditions by chance alone.

Figure 1A shows that compound 10 induced complete GSPT1 degradation in cells treated at a concentration of 0.3 µM. In contrast, none of the known the substrates IKZF1, IKZF3, SALL4, CK1alpha was degraded at the highest concentration tested of 30 µM. In addition, mass spectrometry-based proteomics analysis of a cancer cell line treated with compound 10 demonstrated that GSPT1 was the most statistically significant downregulated protein (Figure 1B).

Example 6: Viability assay and GSPT1 degradation in representative in NSCLC cell lines

The anti-proliferative activity of compound 10 was tested on representative N-Myc high and N-Myc low cell lines (NCI-H1155, ABC-1 and EBC-1, NCI-H2023, respectively) following treatment with compound for 72 hours. Cells were sub-cultures as recommended by the providers (ATCC, DSMZ) and incubated at 37°C, 5% CO_2. All cells were authenticated and confirmed by Short Tandem Repeat (STR) profiling. Briefly, cells were seeded to the appropriate density to allow logarithmic growth over the assay period in 96-well opaque-walled clear bottom plates (from Corning, Cat. No. 3903, Lot. No. 16419061; 100 µL total volume) and incubated overnight. Compound 10 and DMSO control were subsequently dispensed to the plates using HPD300 and a 9 data-point titration curve with concentrations ranging from 30 µM to 0.1 nM. Dilutions were prepared fresh prior to the assay using a 10 mM DMSO stock. Final DMSO concentration was 0.5%. The plates were incubated for 3 days

at 5% CO_2, 37°C. Cell viability was assessed using the CellTiter-Glo assay kit as recommended by the Manufacturer (Promega, Cat. No. G7558, Lot. No. 0000385738) and measurements performed on the EnSpire multimode plate reader (Perkin Elmer). EC50 values were determined using Prism8 (GraphPad) and the asymmetric (five-parameter) equation and least squares fit. GSPT1 levels were assessed in the NCI-H1155 and ABC-1 cell lines by densitometry analysis following treatment with compound 10 for 6 hours and western blotting analysis. Briefly, cells were rinsed with PBS and lysed using 50 µL RIPA lysis buffer (Pierce 8990) supplemented with protease and phosphaste inhibitors (Sigma P8340, Sigma 5726, and Sigma 0044). Primary antibody (human GSPT1, Sigma HPA052488) was diluted in blocking buffer (dil. 1/5000) and incubated with the membranes overnight at 4°C. After two rinses with 1x TBST and two washes with 1x TBST (10 minutes each with shaking at room temperature), HRP-coupled secondary antibody (Invitrogen, A16110, dil. 1/5000) and DyLight680-coupled GAPDH antibody (Invitrogen, MA5-15738-D680, dil. 1/2500) were diluted in blocking buffer, added to membranes and incubated with shaking for at least 45 minutes at room temperature protected from light. Membranes were then transferred between two clean sheets of plastic and chemiluminescence (GSPT1), Dylight680 fluorescence (GAPDH) as well as colorimetric (molecular weight standard) signals were detected using a Chemidoc MP imaging system (BioRad 17001402). For chemiluminescence and colorimetric signals "optimal automatic exposure" settings (3x3 binning) were employed while fluorescence was detected using 1-4 seconds exposure time to achieve best GAPDH signals and avoid overexposure. For image analysis "Image Lab" software (BioRad version 6.0.1) was used. If automatic lane and band detection failed, lanes and bands were indicated manually. Default background correction settings were used. Relative GSPT1 protein levels were calculated by setting GSPT1 levels in vehicle (DMSO)-treated control samples to 100% and normalized to the GAPDH singlas. Dose response data was visualized and a four-parameter non-linear regression curve fitting algorithm (Graphpad Prism version 8.3.0) was used to calculate DC_{50} (value corresponding to 50% reduction in GSPT1 total levels).

Complete degradation of GSPT1 by compound 10 was observed after six hours of treatment in high N-Myc NCI-H1155 and ABC-1 cells with a DC50 of 3 nM and 22 nM, respectively. Compound 10 sensitivity correlated with the expression of N-Myc in the NSCLC cell line (Figure 2A). Degradation took place in a concentration dependent manner (Figure 2B).

MDA-MB-231 cells (human breast adenocarcinoma) were maintained *in vitro* in DMEM medium supplemented with 20% heat inactivated FBS at 37°C in an atmosphere of 5% CO_2 in air. Cells (10 millions) resuspended in 0.2 mL of PBS with Matrigel (50:50) were inoculated into female BALB/c nude mice and allowed to grow to 150 mm^3 in size. Mice were dosed daily *i.p.* with vehicle or a representative compound of the disclosure (0.3, 1 and 3 mg per kilogram *p.o.*). Compound formulations were prepared fresh daily in 5% DMSO / 95% (30% HP-β-CD in purified water). Mice were dosed for 21 days and tumor volumes measured every 3 days. Highest tumor growth was observed in mice having received administration of vehicle only. Tumor growth was reduced by administration of increasing amounts of a representative compound of the disclosure. No tumor growth or a reduction in tumor size was observed when administering 1 mg/kg or less of a representative compound of the disclosure.

Example 8 *In vivo* efficacy studies in N-Myc high NSCLC and SCLC cell lines

For the NCI-H1155 xenograft study, cells (human non small cell lung cancer, ATCC CRL-5818) were maintained *in vitro* as suspension culture in ATCC-formulated DMEM:F12 Medium supplemented as recommended by the provider and kept at 37°C in an atmosphere of 5% CO_2 in air. Cells (0.5 millions) were resuspended in 0.2 mL of PBS with Matrigel (50:50) and inoculated into female BALB/c nude mice, 6-8 weeks old, and allowed to grow to 150 mm^3 in size. Mice were dosed orally with either vehicle or compound 10 at 1 or 3 mg per kilogram daily (filled squares and filled triangles, respectively) or 6 mg per kilogram for 5 continous days followed by 9 days treatment holidays (5 On – 9 off) (filled inverted triangles). Compound formulations were prepared fresh daily in 5%vDMSO / 95%(30% w/v HP-β-CD in water). Gemcitabine dosed at 40 mg per kilogram, IP, Q4Dx5 was used as a positive control (filled rhombi). For this study, mice were dosed for 21 days with tumor volumes measured every 3 days. Results are shown in Figure 3A for compound 10 (x-axis: days; y-axis: tumor volume in mm^3) and indicate that oral administration of compound 10 in a N-Myc-driven mouse xenograft model using the human cell line NCI-H1155 led to tumor growth inhibition (with no body weight loss observed). At a dose of 1 mg/ kg once daily, tumor growth was suppressed for two weeks. At a dose of 3 mg/kg once daily or 6 mg/kg dosed for five days on and nine days off, tumor size decreased, became undetectable by day eight and remained so until the end of the study at day 21.

GSPT1 levels in tumors were determined by western blotting 6 hours after the third dose. Western blotting was performed as described previously using GAPDH as loading control.

Complete degradation of GSPT1 was observed in tumors of mice treated with compound 10 at all three dose levels as compared to mice treated with vehicle control (Figure 3B).

For the NCI-H1770 study, cells (human non small cell lung cancer, ATCC CRL-5893, Lot No. 5188933) were maintained *in vitro* as suspension culture in ATCC-formulated RPMI-1640 Medium supplemented by 10% FBS and cultured at 37°C in an atmosphere of 5% CO_2 in air. Cells (10.0 millions) were resuspended in 0.2 mL of PBS with Matrigel (50:50) and inoculated into female BALB/c nude mice, 6-8 weeks old, and allowed to grow to 150 mm^3 in size. Mice were dosed orally with either vehicle (empty circles) or compound 10 at 3 mg per kilogram daily or 6 mg per kilogram for 5 continous days followed by 9 days treatment holidays (5 On – 9 off) (filled triangles and filled inverted triangles, respectively). Compound formulations were prepared fresh daily in 5%vDMSO / 95%(30% w/v HP-β-CD in water). Cisplatin dosed at 6 mg per kilogram, IP, QWx3 was used as a positive for this model (filled rhombi). Mice were dosed for 21 days with tumor volumes measured every 3 days. Similar results were observed as for NCI-H1155 as shown in Figure 3C for compound 10 (x-axis: days; y-axis: tumor volume in mm^3).

For the NCI-H526 study, cells (human small cell lung cancer, ATCC CRL-5811) were maintained *in vitro* as suspension culture in ATCC-formulated RPMI-1640 Medium supplemented with 10% FBS and cultured at 37°C in an atmosphere of 5% CO_2 in air. Cells (2.5 millions) were resuspended in 0.2 mL of PBS with Matrigel (50:50) and inoculated into female BALB/c nude mice, 6-8 weeks old, and allowed to grow to 150 mm^3 in size. Mice were dosed orally with either vehicle (empty circles) or compound 10 at 3 mg per kilogram daily or 6 mg per kilogram for 5 continous days followed by 9 days treatment holidays (5 On – 9 off) (filled triangles and filled inverted triangles, respectively). Compound formulations were prepared fresh daily in 5%vDMSO / 95%(30% w/v HP-β-CD in water). Cisplatin dosed at 6 mg per kilogram, IP, QWx3 was used as a positive for this model (filled rhombi). Mice were dosed for 21 days with tumor volumes measured every 3 days. Similar results were observed as for NCI-H1155 as shown in Figure 3D for compound 10 (x-axis: days; y-axis: tumor volume in mm^3).

Example 9: HTRF Binding of compounds to CRBN and Activity for GSPT1 degradation.

Compound activity was monitored in a Homogenous Time-Resolved Fluorescence (HTRF) assay using 1-[5-({2-[2-(2-{[2-(2,6-dioxopiperidin-3-yl)-1,3-dioxo-2,3-dihydro-1H-isoindol-4-yl]oxy}acetamido)ethoxy]ethyl}carbamoyl)pentyl]-3,3-dimethyl-2-[(1*E*,3*E*)-5-

[(2*E*)-1,3,3-trimethyl-5-sulfo-2,3-dihydro-1H-indol-2-ylidene]penta-1,3-dien-1-yl]-3H-indol-1-ium-5-sulfonate as a fluorescent probe. Biochemical assays were conducted in Greiner white 384 well HiBase plates (Cat. No 784075-25) in 10 µL total volume. A one pot detection solution of CRBN-DDB1 (2.5 nM), Anti-His Terbium Cryptate Gold (1X, PerkinElmer Cat.#: 61HI2TLB), and Cy5-Thalidomide (100nM, Tenova Cat.: T52461) was prepared in 20 mM HEPES, 20 mM NaCl, 0.2 mM TCEP, 0.2 mM EDTA, and 0.005% Tween20 was dispensed to each assay plate. Compounds were stored in dry, ambient temperatures at 10 mM. A 10-point, 1:3 dilution series was prepared from 10 mM stock concentrations in Echo-compatible LDV plates. 10nL of each compound dilution series was dispensed into assays wells using an Echo 650 (Labcyte inc. USA). 10 nL of 10 mM Lenalidomide was transferred into the active-control wells for the assay and 10 nL of DMSO was transferred into the neutral-control wells. The assay was then allowed to incubate for 30 min at ambient temperature after transferring compound. Plate measurements were taken on a Pherastar FSX (BMG Labtech, Germany) using the HTRF Red filter (Ex. 337 nm, em1: 620 nm, em2: 665 nm) (Flashes: 50, Integration time: 60-400 us, Z-height: 10 mm, Ratio-multipler: 10,000). The HTRF signal was then subsequently normalized to the neutral and active controls. Analysis and IC50 values were derived using KNIME analytics (KNIME Zurich) transformation and fitting within Collaborative Drug Discovery (Collaborative Drug Discovery USA). Ki was derived from the geometric mean of the IC50 values using the Cheng-Prustoff transformation.

Example 10: Compound Activity by Immunofluorescence assay.

The representative compounds were tested in an immunofluorescence assay for their activity to degrade GSPT1. CAL-51 cells were purchased from DSMZ (cat. Number ACC302), sub-cultured in 90% Dulbecco's MEM (4.5 g/L glucose, Gibco 11965) + 10% heat inactivated FBS (BioConcept, 2-01F136I) and incubated at 37 °C, 5% CO_2. For the assay imaging microtiter plate Cell Carrier 96 Ultra (Perkin Elmer 6055302) were pre-coated with Fibronectin (Sigma F085, 30 µl at 0.2 µg/ml) in PBS (100 µL, Gibco 14190) for 45 min at room temperature, rinsed with PBS and CAL-51 cells (30K cells/well) were plated and let to adhere overnight. Cells were treated with compounds typically using a serial dilution ranging from 30 µM to 0.1 nM for 6 h. Compounds were stored at 10 mM DMSO stocks. Vehicle (DMSO), positive (CC-885, 10 µM) and rescue controls (positive control plus 0.2 µM

bortezomib) were also included at this stage. Cells were subsequently rinsed with PBS and fixed in 10% Formalin solution (50µl, Sigma HT5011)) for 20 mins at room temperature. Following three consecutive PBS washes (100 µL), cells were permeabilized in 0.1% Triton X-100 in PBS (Sigma 93443, 50 µL) for 15 min. at room temperature. Following three further PBS washes, 50 µL blocking buffer (1% BSA, Sigma A4503, in PBS) was added for 45 min for signal-to noise reduction. Primary antibody (human GSPT1, Sigma HPA052488) was diluted in blocking buffer (dil.1/300, 35µL/well) and incubated with the cells overnight at 4 °C. After three PBS washes, Alexa-fluor 488 coupled secondary antibodies (Invitrogen, A32731, dil.1/1000), Alexa-fluor 647-Phalloïdin (Invitrogen, A22287, dil.1/200) and DAPI (Thermo, #62248, dil.1/1000) were diluted in blocking buffer and incubated with the samples for 2 h at room temperature. After three final PBS washes, samples were conserved in 100 µL PBS in the dark, until measurement. Image acquisition was performed on the Operetta High-Content Imager (Perkin-Elmer). Fluorescence intensity of Alexa-F 5 luor 488 (GSPT1), Alexa-Fluor 647 (Actin) and DAPI (Nucleus) were measured. For the determination of GSPT1 DC50 values, a custom algorithm implemented in the PerkinElmer image analysis software Harmony-Acapella® was developed. After user-defined setting of adjustment parameters, the analysis was run identically without human intervention for all image fields. DAPI staining of the nuclei was used to determine the location of cells using standard nuclei detection modules. Segmentation artifacts were removed by threshold-based filters for area, roundness and intensity. The outline of the cells was determined analogously from the sum of the normalized, smoothed DAPI and Actin channel, starting from each nucleus. The Alexa-Fluor 488 (GSPT1) signal intensity in each cell was finally measured, in order to obtain a Mean intensity per cell. GSPT1 degradation (DC50) was calculated after normalization to controls and data import in CDD vault Database, using non-linear regression.

In Table 5 each compound is assigned a class (HTRF class) indicating the ability for Cereblon binding by means of their HTRF IC50 values according to Example 9: A, B, C or D. According to the code, A represents an IC50 value of ≤100 nM, B represents an IC50 value >100 nM and ≤1000 nM, C represents an IC50 value >1000 nM. IF Class assigns each compound a code indicating the ability for GSPT1 degradation: A, B or C. According to the code, A

represents a DC50 value of ≤30 nM, B represents a DC50 value > 30 nM and ≤300 nM and C represents a DC50 value of >300 nM. The IF data were obtained according to Example 10.
