(57) **ABSTRACT**

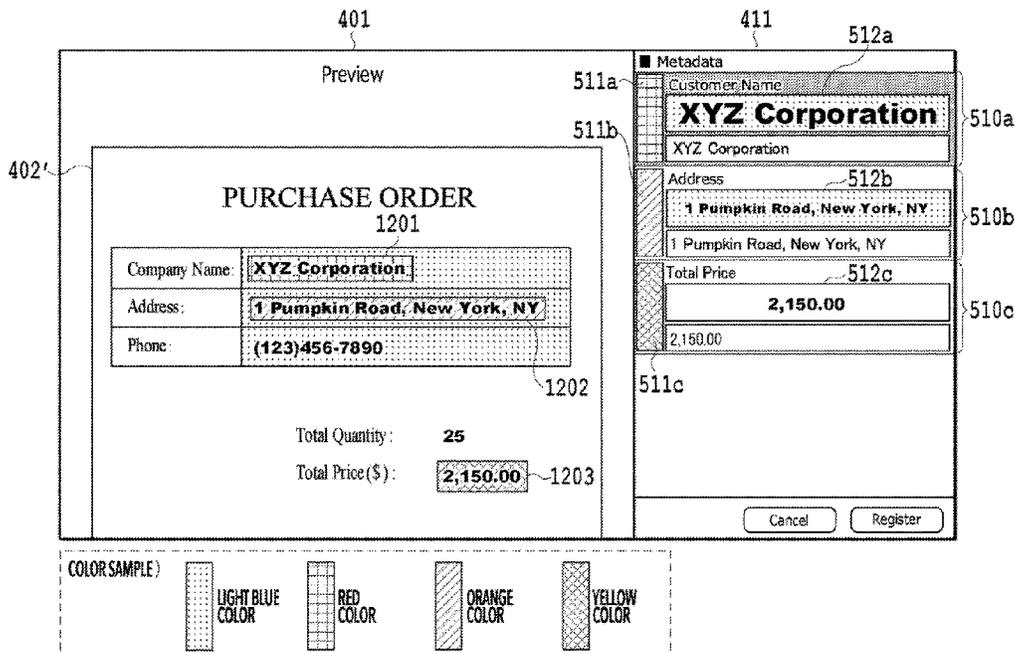

Coordinated colors are used to make it easy for a user to grasp with which text block within a preview pane a setting item within a property pane is associated. By using a color allocated to a setting item displayed in the property pane, at least a part of a display field corresponding to the setting item is colored. Then, in a case where a user selects one of text blocks in a scanned image preview-displayed in the preview pane in the state where one of setting items is selected in the property pane, the text block is colored by using a color allocated to the setting item in the selected state.

BACKGROUND

Field

The present disclosure relates to a graphical user interface (GUI) at the time of computerizing a document and making use of the computerized document.

Description of the Related Art

Conventionally, it has been performed to extract a character string by performing optical character recognition processing (OCR processing) for a scanned image obtained by scanning a business form, such as an order sheet, and make use of the character string as a file name or the like. Japanese Patent Laid-Open No. 2019-115011 has disclosed a technique to automatically generate a file name by extracting a character string including a specific key from character strings included within a document image and present the file name to a user along with a preview display of the document image. With this technique, it is possible for a user to easily set a file name while checking the document image. Then, it is also performed to save and manage a character string extracted from a scanned image as metadata and make use of the metadata as a file name or the like.

As the configuration of a UI screen of an application at the time of setting a file name or metadata by using a recognized character string obtained by OCR processing, a two-pane configuration including a preview pane and a property pane is well known. Here, the preview pane is an area for preview-displaying a computerization-target scanned image and the property pane is an area for displaying contents of a property, such as a file name and metadata, in a list. In a case where a document, such as an order sheet or a bill, is computerized, a plurality of character areas (text blocks) is included in the scanned image and it is possible for a user to visually recognize each text block by the preview pane. Further, by the property pane, it is possible for a user to check the contents of a variety of setting items, such as "Customer Name", "Date", and "Address". For example, it is assumed that a user selects a text block of "XYZ Corporation" within the preview pane for a setting item of "Customer Name" within the property pane on the above-described two-pane configuration UI screen. As a result of that, the recognized character string "XYZ Corporation" within the scanned image is saved in association with the setting item "Customer Name". In this case, on a condition that a plurality of text blocks exists within the preview pane and a plurality of setting items exists also within the property pane, it is difficult for a user to immediately grasp which block is associated with which setting item.

The present disclosure has been made in view of the above-described problem and an object is to make it possible for a user to easily grasp the correspondence relationship between a text block and a setting item on a UI screen having a preview pane and a property pane.

SUMMARY

The image processing system that computerizes a document according to the present disclosure includes: a memory that stores a program; and a processor that executes the

program to perform: displaying a user interface screen for setting a property to a scanned image obtained by scanning the document; and controlling a display on the user interface screen, and on the user interface screen, at least a preview pane that is an area preview-displaying the scanned image and a property pane that is an area to which a setting value of each setting item of the property is input exist, and wherein at least a part of a field of a setting item displayed in the property pane and a text block corresponding to the setting item in the scanned image preview-displayed in the preview pane are colored with a same color or similar colors.

Further features of the present disclosure will become apparent from the following description of exemplary embodiments with reference to the attached drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a diagram showing an entire configuration of an image processing system;

FIG. 2 is a block diagram showing a hardware configuration of an information processing apparatus;

FIG. 3 is a diagram showing a software configuration of the image processing system;

FIG. 4A is a diagram explaining a state transition of a UI screen;

FIG. 4B is a diagram explaining an orthogonal coordinate system;

FIG. 5 is a diagram explaining a state transition of a UI screen;

FIG. 6 is a flowchart showing a flow of UI screen control processing according to a first embodiment;

FIG. 7 is a diagram explaining a problem of a modification example 2;

FIG. 8 is a diagram explaining effects of the modification example 2;

FIG. 9 is a flowchart showing details of coloring control processing according to the modification example 2;

FIG. 10A is a diagram explaining similarity determination of a color and FIG. 10B is a diagram explaining a change in an item color;

FIG. 11 is a flowchart showing details of coloring control processing according to a modification example 3;

FIG. 12 is a diagram explaining effects of the modification example 3;

FIG. 13 is a flowchart showing a flow of UI screen control processing according to a second embodiment;

FIG. 14 is a diagram explaining a state transition of a UI screen; and

FIG. 15 is a diagram explaining a state transition of a UI screen.

DESCRIPTION OF THE EMBODIMENTS

Hereinafter, with reference to the attached drawings, the present disclosure is explained in detail in accordance with preferred embodiments. Configurations shown in the following embodiments are merely exemplary and the present disclosure is not limited to the configurations shown schematically.

First Embodiment

<System Configuration>

FIG. 1 is a diagram showing the entire configuration of an image processing system that computerizes a document according to the present embodiment. The image processing system includes a scanned document processing server 111,

a client terminal **121**, and a work server **131**. The client terminal **121** is connected with the scanned document processing server **111** and the work server **131** so as to be capable of communication via a network **101**, such as an interne and an intranet. The client terminal **121** may be an MFP (Multifunction Peripheral) and the like comprising the scanner function, in addition to a personal computer, a laptop computer, a tablet computer, a smartphone and the like. The configuration of the image processing system shown in FIG. **1** is an example, but the configuration is not limited to this. For example, it may also be possible for the client terminal **121** to have the function of the scanned document processing server **111**. In the following explanation, a scanned image obtained by scanning a processing-target document, such as an estimate form, is called "scanned document".

<Hardware Configuration>

FIG. **2** is a block diagram showing the hardware configuration of the scanned document processing server **111**, the client terminal **121**, and the work server **131**, each as an information processing apparatus. A user interface (UI) **201** is implemented by a display, a keyboard, a mouse, a button, a touch panel and the like and inputs and outputs information and signals. It is also possible for a computer not comprising the hardware such as this to connect and operate from another computer by a remote desktop, a remote shell, and the like. A network interface **202** connects to the network **101** and performs communication with another information processing apparatus and a network device, not shown schematically. The communication method may be wired or wireless. A CPU **203** is a computing device in charge of the control of the entire apparatus and executes programs read from a ROM **204**, a RAM **205**, a secondary storage device **206** and the like. The ROM **204** stores incorporated programs and various kinds of data. The RAM **205** temporarily stores various kinds of data and also functions as a work memory of the CPU **203**. The secondary storage device **206** is a large-capacity storage device represented by an HDD and a flash memory. Each of the units described above is connected to one another via an input/output interface **207**.

<Software Configuration>

FIG. **3** is a diagram showing the software configuration of the image processing system according to the present embodiment. Each piece of software is installed in the scanned document processing server **111**, the client terminal **121**, and the work server **131**, respectively, described above and executed by the CPU **203** of each apparatus. In the following, each piece of software is explained.

<<Software of Scanned Document Processing Server>>

A scanned document processing application **311** is a Web application installed in the scanned document processing server **111**. However, the scanned document processing application **311** may be in an application mounting form other than a Web application. An API **312** is an API (Application Programming Interface) provided by the scanned document processing application **311**. A Web UI **313** is a Web user interface provided by the scanned document processing application **311**.

A data store **321** is a storage area saving and storing data that is used by the scanned document processing application **311** or a backend application **331**, to be described later. In the data store **321**, a scanned document storage unit **322**, a scanned document job queue **323**, a property management unit **324**, and a scanned image processing results storage unit **325** exist. The scanned document storage unit **322** files the data of a scanned image itself and saves as an image file, such as JPEG, or a document file, such as PDF (Portable

Document Format). The scanned document job queue **323** stores a queue managing jobs to be subjected to property input processing, to be described later. The property management unit **324** manages a list of setting items and a format of a name or a value (character string, figure, and the like) for each setting item, relating to properties, such as a file name, a folder path, and metadata, which need to be attached for each scanned document, item color information, to be described later, and the like. The scanned document processing results storage unit **325** stores OCR processing results and business form determination results. Further, the scanned document processing results storage unit **325** stores character area information (text block information) associated with a setting item, a set value, and the like for each scanned document.

The backend application **331** is an application for performing background processing. The backend application **331** is an application in charge of various kinds of processing that may be performed sequentially on the background, specifically, OCR processing, business form processing, and communication processing. An OCR processing unit **332** acquires a processing-target scanned document from the scanned document storage unit **322** and performs OCR processing for the acquired scanned document. In the OCR processing, information specifying each text block (specifically, information on the start point coordinates, width, height of a rectangular area) and information on a recognized character string of each text block are extracted. A business form processing unit **333** determines the type of the scan-target document (business form) by using the information on the processing-target scanned document, the arrangement pattern of text blocks and the recognized character strings, which are obtained by the OCR processing. This determination processing may be any method, such as pattern recognition and machine learning. A communication processing unit **334** performs processing to transmit a scanned document and analysis processing results thereof to the work server **131**, which is an external apparatus. In a case where it is not necessary to transmit a scanned document and analysis processing results thereof, the communication processing unit **334** may be omitted.

<<Software of Client Terminal>>

A client application **351** performs the Web application of the above-described scanned document processing application **311**. For example, the client application **351** performs the Web application by displaying the Web UI **313** by a Web browser and performing transmission and reception of necessary data with the API **312**.

<<Software of Work Server>>

A work application **361** is an application for assisting various kinds of work in a company, such as file management, document management, order reception, and accounting. A work data storage **362** saves various kinds of data used by the work application **361**. The work application **361** receives results of processing by the scanned document processing server **111** and performs necessary processing for the results and stores the results.

<UI Screen of Client Application>

Following the above, a user interface screen (hereinafter, described as "UI screen") that is displayed on the user interface **201** of the client terminal **121** is explained. FIG. **4A** shows an example of a UI screen that is displayed on the user interface **201** by the client application **351** according to the present embodiment.

The UI screen shown in FIG. **4A** has a two-pane configuration of a Preview pane **401** and a Property pane **411**. Here, within the Preview pane **401**, a page image **402** of a scanned

5

document of "PURCHASE ORDER" is preview-displayed. In the Preview pane 401, it is possible to display any position in the page image 402 by scrolling or zooming the page image 402. The Property pane 411 is a pane for displaying and editing a property to be attached to the processing-target scanned image. Items that are set as properties include master items, such as "File Name", "Folder Path", and "Metadata", and slave items, such as "Company Name", "Date", and "Address", which are elements configuring the master items. Explanation below is given by taking a case as an example where "Metadata" is set and registered as the master item.

The UI screen in FIG. 4A is an example in a case where the business form type of the processing-target scanned document is determined to be "PURCHASE ORDER" in the business form determination processing. Then, the state is such that three slave items "Customer Name", "Address", and "Billing Name" are displayed as the contents of the master item "Metadata" to be attached to the scanned document. In the following explanation, the slave item of the metadata is called "metadata item".

FIG. 4B is a diagram explaining an orthogonal coordinate system indicating a relationship between the page image 402 and each text block. In FIG. 4B, three text blocks 421, 422, and 423 exist. In the page image 402, there are more text blocks, but they are omitted here. The text block detected by OCR processing is identified respectively by the start point coordinates, width, and height as shown by a hatched rectangle. For example, the text block 423 corresponding to the character string of "XYZ Corporation" is represented as "Start point coordinates (1200, 700)", "Width: 720" and "Height: 120" in units of pixels.

FIG. 5 is a diagram explaining the way a text block within the page image 402 is associated with the metadata item on the UI screen in FIG. 4A. Here, the state is such that a text block 501 corresponding to the character string of "XYZ Corporation" within the page image 402 and the metadata item "Customer Name" (item of 510a) are associated with each other. Then, in order to enable a user to easily identify, on the text block 501, a rectangle colored in a color (in the example in FIG. 5, "red color" allocated to the metadata item "Customer Name") allocated to each metadata item based on item color information is displayed in a transparent and superimposing manner. The coloring method is not limited to the transparent and superimposed display and may be a superimposed display or the like by a colored frame line. Horizontally elongated rectangles 510a to 510c within the Property pane 411 are display fields in which setting values and the like of the metadata items, which are slave items, are displayed and edited for the metadata, which is the master item. Further, vertically elongated rectangles 511a to 511c are item color areas that are each provided at a portion within the display field and which each display a color (item color) allocated to each metadata item so as to enable a user to identify the color. Then, horizontally elongated rectangles 512a to 512c are each an area (cut-out image area) in which an image (image cut out from the page image 402) corresponding to the text block selected by a user is displayed. In the stage in which association with any text block is not performed yet, the state is such that a "+" button is displayed as in the cut-out image areas 512b and 512c and the item colors of the item color areas 511b and 511c are not displayed. Horizontally elongated rectangles 513a to 513c located under each of the cut-out image areas 512a to 512c are each an editing area in which the recognized character string included in the text block relating to user selection is

6

displayed and it is possible for a user to edit the displayed contents with a soft keyboard or the like, not shown schematically.

<UI Screen Control Processing>

Next, control processing to associate a text block with each metadata item on the UI screen described above, which is performed by the client application 351 of the client terminal 121, is explained by using a flowchart in FIG. 6. Prior to the start of execution of the flow shown in FIG. 6, first, a queue of jobs to be processed is provided to the client application 351 by the scanned document processing application 311 of the scanned document processing server 111. In a case where a user selects a job of a scanned document for which the user desires to start processing by using the client application 351, the scanned document processing application 311 acquires necessary information corresponding to the selected scanned document from the data store 321. Specifically, the scanned document processing application 311 acquires the corresponding image file from the scanned document storage unit 322 and acquires the corresponding OCR processing results and business form type determination results from the scanned document processing results storage unit 325. Further, the scanned document processing application 311 acquires the metadata item list for each business form type and the item color information for identifying a predetermined color allocated in advance for each metadata item from the property management unit 324. These pieces of acquired data are provided to the client application 351 from the scanned document processing application 311 and the flow in FIG. 6 is started. In the following explanation, symbol "S" represents a step.

At S601, the data of the page image and the OCR processing results (recognized character string) is loaded, which are to be displayed within the Preview pane 401. At S602 that follows, the metadata item list corresponding to the business form type and the item color information are loaded. At next S603, the contents of the data loaded at S601 and S602 are reflected on the UI screen. Specifically, the page image is displayed within the Preview pane 401 and each metadata item included in the metadata item list is displayed within the Property pane 411. By the processing at S601 to S603 performed so far, the state of the UI screen shown in FIG. 4A is brought about. At this point in time, coloring to the item color areas 511a to 511c of each metadata item within the Property pane 411 is not performed yet and the item color areas 511a to 511c are in the default (for example, gray) state. The reason is to present that metadata is not set yet to a user in an easy-to-see manner and prompt the user to set metadata by representing visually that coloring is not determined yet, together with the "+" button display in the cut-out image area 512 described previously.

Then, at S604, an operation event of the selection operation of the "+" button of the cut-out image areas 512a to 512c in one of the metadata items within the Property pane 411 is detected. This selection operation is an operation of a user touching or the like the "+" button on the touch panel with a finger or a touch pen, or a click operation with a mouse. In this manner, one metadata item relating to the user selection is determined among one or a plurality of metadata items included in the metadata item list. In the following, the metadata item selected by a user is called "selected metadata item". At S605 that follows, the item color area of the selected metadata item determined at S604 is colored in accordance with the item color information loaded at S602. Here, it is assumed that in the item color information, a specific color is associated with the order of each slave item existing within the master item. For example, four colors of

blue, green, yellow, and red are defined in advance as usable colors and the item order and the color are associated with each other in advance, such as that the first setting item is associated with “blue”, the second setting item with “green”, the third setting item with “yellow”, and the fourth setting item with “red”. In this case, the three slave items of “Customer Name”, “Address”, and “Billing Name” of the master item “Metadata” are in this order, and therefore, “blue”, “green”, and “yellow” are allocated, respectively, as the item colors. By associating a specific color with the order of a plurality of setting items as described above, it is possible to make common the item color information in a variety of kinds of setting item. It may also be possible to allocate in advance a specific color to each individual specific setting item in the item color information. Further, by highlighting the display field of the selected metadata item for which the selection operation has been performed by a user, for example, such as changing the color of the area other than the item color area within the display field, it is made easier for a user to identify the metadata item currently being selected. As a method of making it possible to identify the metadata item currently being selected is not limited to the method of changing the color, and for example, it may also be possible to highlight the display field of the metadata item by surrounding the display field with a thick-line frame.

Then, at S606, an operation event is detected, such as a touch operation to one of text blocks existing in the page image 402 within the Preview pane 401. In this manner, one arbitrary text block is selected from one or a plurality of text blocks included in the page image. In the following, the text block selected by a user is called “selected text block”. At S607 that follows, the selected text block determined at S606 is colored in the same color as that in which coloring has been performed to the item color area within the selected metadata item colored at S605. Then, at S608, the cut-out image corresponding to the selected text block colored at S607 is displayed in the cut-out image area within the selected metadata item. Further, the recognized character string included in the selected text block colored at S607 is displayed within the editing area of the selected metadata item determined at S604. By the processing at S604 to S608 performed so far, the state of the UI screen as shown in FIG. 5 is brought about. That is, the metadata item selected by a user and the text block are associated with each other and which text block is used to input the character string used in the selected metadata item is determined.

In a case where the above processing is completed for all the metadata items within the metadata item list and a “Register” button 514 is touched by an operation of a user, at S609, a request to register metadata is transmitted to the scanned document processing server 111. In this metadata registration request, information associating edited values in all the metadata items and the text blocks with each other is included. In the scanned document processing server 111, the scanned document processing application 311 saves the above-described information included in the metadata registration request received from the client terminal 121 in the scanned document processing results storage unit 325. At this time, in a case where the registration of metadata is performed in the external work server 131, the metadata registration request is transferred to the work server 131 via the communication processing unit 334. After all the necessary processing is completed, the scanned document processing application 311 dequeues the queue from the scanned document job queue 323. In this manner, this processing is completed.

The above is the contents of the UI screen control processing in the client application 351 according to the present embodiment. In the present embodiment, the item color area indicating the color allocated for each setting item is provided for each display field of each setting item, but it is not mandatory to provide each individual item color area. That is, it may also be possible for the area (area except for the cut-out image area and the editing area in each display field) for the highlight indicating that the setting item is selected by a user to display an item color. In a case where the configuration is made so that the item color is displayed in the area except for the cut-out image area and the editing area within each display field, as the highlight indicating that a user has selected the setting item, it is sufficient to produce the highlight by, for example, attaching a thick-line frame that surrounds the selected display field, changing the density of the color, and so on.

Modification Example 1

In the flow in FIG. 6 described above, at the timing (S605) of the highlight accompanying the selection of the metadata item of interest by a user (detection of touch operation to the “+” button within the cut-out image area), the coloring to the item color area is performed. However, the timing of coloring to the item color area is not limited to this. For example, it may also be possible to perform coloring to the item color area within the selected metadata item at the same timing as that of coloring to the selected text block at S607.

Modification Example 2

In the flow in FIG. 6 described above, by coloring the selected text block within the Preview pane in the same color as that of the item color area of the selected metadata item, it is made possible for a user to grasp the correspondence relationship between the metadata item and the text block. At this time, there is a possibility that the color used for coloring and the character color or the background color within the selected text block are similar to each other. In this case, the visual recognizability of the color used for coloring to the selected text block is degraded. Consequently, an aspect is explained as a modification example 2 in which the color used for coloring is changed as needed.

FIG. 7 is a diagram explaining a problem of the present modification example, which corresponds to FIG. 5 described previously. In a page image 402' in FIG. 7, three character strings “XYZ Corporation”, “1 Pumpkin Road, New York, N.Y.”, and “(123) 456-7890” whose character color is black are surrounded by ruled lines and the background color in the light blue color is attached to the inside thereof. Here, the state is such that a text block 701 corresponding to the character string of “XYZ Corporation” within the page image 402' and the metadata item “Customer Name” are associated with each other. Then, among the three metadata items, “Customer Name” is the first setting item, and therefore, the blue color is displayed in the item color area 511a within the display field 510a thereof. As a result of that, the light blue color, which is the background color within the ruled lines surrounding the character string of “XYZ Corporation”, and the blue color used for coloring to the text block 701 are similar to each other (similar colors). In this situation, it is difficult for a user to grasp that the text block 701 and the metadata item “Customer Name” are associated with each other.

FIG. 8 is a diagram explaining effects in a case where the present modification example is applied. As in FIG. 7, the

state is such that the text block 701 corresponding to the character string of “XYZ Corporation” within the page image 402 and the metadata item “Customer Name” are associated with each other. However, in FIG. 8, in the item color area 511a of the metadata item “Customer Name”, the red color is displayed in place of the original blue color. As a result of that, between the light blue color, which is the background color within the ruled lines surrounding the character string of “XYZ Corporation”, and the red color in which the text block 701 is colored, a contrast in color occurs, and therefore, it is made possible for a user to easily grasp the association.

Here, details of the processing to control coloring to the setting item and the text block according to the present modification example are explained with reference to the flowchart in FIG. 9. The coloring control processing shown in the flow in FIG. 9 is performed in place of S 607 in the flow in FIG. 6 described previously.

At S901, the information on the character color of the character string included in the selected text block for which the operation event has been detected at S606 and the background color of the text block is acquired from the scanned document processing results storage unit 325 via the scanned document processing application 311. Here, explanation is continued on the assumption that information on values (R, G, B=0, 5, 5) indicating black as the character color and values (R, G, B=188, 213, 254) indicating light blue as the background color is acquired.

At S902, information on the color used for coloring based on the item color information at S605 (that is, the color allocated as the item color of the selected metadata item and used for coloring to the item color area) is acquired. It is assumed that allocation of “blue” to the first setting item, “green” to the second setting item, “yellow” to the third setting item, and “red” to the fourth setting item is defined as the default contents in the item color information in the present modification example. Here, in a case where the first “Customer Name” is selected among the three metadata items within the Metadata pane 411, the item color area is colored in “blue”, and therefore, in this case, information (for example, RGB values) indicating “blue” is acquired.

At next S903, the color allocated as the item color of the selected metadata item and the character color and the background color within the selected text block are compared and whether they are similar to each other is determined. For example, as shown in FIG. 10A, the RGB values of the color allocated as the item color of the selected metadata item and the RGB values of the character color and the background color acquired at S901 are compared, respectively, and whether the difference therebetween is within a predetermined threshold value is determined. At this time, it is desirable to set a threshold value by which, for example, the light blue color or the purple color, whose hue is close to that of the blue color, is determined to be “similar” to the blue color. Here, it is assumed that the blue color allocated as the item color of the selected metadata item “Customer Name” is determined to be similar to the light blue color, which is the background color of the selected text block. In a case where the color allocated as the item color for the selected metadata item is determined to be similar to the character color or the background color within the selected text block in this manner, the processing advances to S904. On the other hand, in a case where it is determined that they are not similar, the processing advances to S905.

At S904, processing to change the color currently allocated as the item color of the selected metadata item to another different color defined in the item color information

is performed. Specifically, the association between the item order and each color in the candidate color information is changed and a different color is allocated to the selected metadata item. In a case of the above-described example, the order of the selected metadata item “Customer Name” is the first. Consequently, as shown in FIG. 10B, the color is changed to the color associated with the fourth selected metadata item (in this case, “red”) whose order is the last and which is not used in the above-described example and at the same time, processing to associate “blue” with the fourth selected metadata item is performed. By exchanging the colors between the first and fourth selected metadata items in this manner, it is possible to maintain the color association between the second and third selected metadata items, and therefore, it is possible to suppress the influence by the change to a minimum. After changing the color that is the item color of the selected metadata item in this manner and updating the item color information in accordance with the change, the processing returns to S903 and the similarity determination is performed again. This processing is repeated until the determination results indicate that the color allocated as the item color is no longer similar to the character color or the background color within the selected text block.

Then, at S905, the display of the color of the item color area of the selected metadata item is updated as needed. That is, in a case where the color allocated as the item color of the selected metadata item is changed to another color at S904, coloring is performed in the newly changed color.

At S906, the selected text block is colored by using the same color as the color being displayed in the item color area of the selected metadata item. Due to this, the state of the UI screen as shown in FIG. 8 described previously is brought about. In a case where coloring is completed, the processing returns to the flow in FIG. 6 and the display processing at S608 is performed.

The above is the contents of the coloring control processing according to the modification example 2. As described in the first embodiment, it may also be possible to perform control so that the coloring to the item color area within the selected metadata item is not performed until the coloring to the selected text block is performed and coloring to both the item color area and the selected text block is performed at the same timing.

Modification Example 3

With an increase in the number of setting items, a case may occur where it is difficult to select a color that is not similar to the character color or the background color from among the colors defined in the item color information and allocate the color. Consequently, an aspect is explained as a modification example 3 in which a color that is the item color of each setting item is determined and allocated without basing the determination and allocation on the item color information.

Details of processing to control coloring to a setting item and a text block according to the present modification example are explained with reference to the flowchart in FIG. 11. It is assumed that the coloring control processing shown in the flow in FIG. 11 is performed in place of S602 in the flow in FIG. 6 described previously. Then, at S605 in the flow in FIG. 6 in a case where the present modification example is applied, coloring to the item color area is performed by using a color determined by processing, to be described later, in place of a color determined based on the item color information.

At S1101, the metadata item list is loaded. That is, in a case of the present modification example, item color information is not loaded. At S1102 that follows, from the OCR processing results loaded at S601, the information on the character colors of the character strings included in all the text blocks within the page image and the background colors of the text blocks is acquired.

At S1103, in the character colors and the background colors acquired at S1102, a chromatic color whose frequency of appearance is high is specified. For example, it is assumed that 100 text blocks exist within the page image and the black color is used as all the character colors. On the hand, as to the background color, it is assumed that there are 80 text blocks for which the white color is used, 18 text blocks for which the light blue color is used, and two text blocks for which the yellowish green color is used. In this case, the chromatic color is the light blue color and the yellowish green color, and therefore, the light blue color whose number of times of use is large is specified as the chromatic color whose frequency of appearance is high. The reason black and white, which are achromatic colors, are excluded is that they are not suitable to the use as the item color aimed at identification because black and white are used generally in a business form and the like.

At S1104, based on the chromatic color that appears frequently, which is specified at S1103, the item color for each metadata item is determined. Examples of a specific determination method are as follows.

A first method is a method that makes use of a hue circle. In this case, with a chromatic color that appears frequently being taken as a reference, a color located at a distant position in the hue circle is determined as the item color for each metadata item. For example, in a case where the chromatic color that appears frequently is the light blue color and this is taken as a reference, the color located at the most distant position in the hue circle is the orange color, and therefore, a color that is allocated as the item color is determined in a predetermined range with the orange color being taken as a center (for example, range from yellow color to purple color). At this time, in a case where a plurality of setting items to which an item color is to be allocated exists and it is necessary to determine a plurality of colors, it is sufficient to select the plurality of colors so that, for example, the intervals in the hue circle are substantially equal in order to distinguish between the plurality of colors.

A second method is a method of determining a color that is not similar to the chromatic color that appears frequently as the item color among a plurality of candidate colors determined in advance. For example, as candidate colors, five colors of red, green, yellow, blue, and purple are determined in advance. Then, in a case where the chromatic color that appears frequently is the light blue color, the color is allocated as the item color sequentially from the remaining four colors (red, green, yellow, purple) except for the blue color similar to the light blue color. It is sufficient to determine the number of candidate colors at this time in accordance with the format or the like of the business form supposed as the processing target. Further, at the time of determining the color to be excluded, it is sufficient to perform the same similarity determination as that explained at S903 of the modification example 2.

The two methods explained above are examples and any method may be used as long as the method is capable of allocating a color a user can easily distinguish from another color as the item color with the chromatic color that appears frequently being taken as a reference.

FIG. 12 is a diagram explaining effects in a case where the present modification example is applied. In this example, the background color within the ruled lines surrounding the character string of "XYZ Corporation" is the light blue color, and therefore, three colors not similar to the light blue color are determined as the item colors and allocated. That is, to the three metadata items "Customer Name", "Address", and "Total Price", the red color, the orange color, and the yellow color are allocated respectively as the item colors. Due to this, the colors used for coloring to three text blocks 1201 to 1203 are conspicuous, and therefore, it is made possible for a user to easily grasp the association between the color and the selected text block corresponding to each selected metadata item.

The above is the contents of the coloring control processing according to the modification example 3. There may be a plurality of colors specified as chromatic colors that appear frequently. Further, it may also be possible to specify a chromatic color that appears frequently by taking only the text blocks existing in a partial area, for example, such as the top portion of the page image, as a target in place of all the text blocks existing within the page image. As in the modification example 2, it may also be possible to perform control so that coloring to the item color area within the selected metadata area is not performed until coloring to the selected text block is performed and coloring to both the item color area and the selected text block is performed at the same timing.

As described above, according to the present embodiment, even in a case where a plurality of text blocks exists within the page image and a plurality of setting items (slave items) exists within the property pane on the UI screen having the preview pane and the property pane, it is possible for a user to easily grasp the correspondence relationship therebetween.

Second Embodiment

In the first embodiment, the UI screen control on the assumption of a case where one-to-one association in which one text block is associated with one metadata item is performed is explained. Next, UI screen control capable of dealing also with a case where one-to-N association in which the same text block is associated with a plurality of metadata items is explained as a second embodiment. Explanation of the contents in common to those of the first embodiment, such as the system configuration, is omitted and in the following, different points are explained mainly.

<UI Screen Control Processing>

The UI screen control processing according to the present embodiment, which is performed by the client application 351 of the client terminal 121, is explained by using the flowchart in FIG. 13. Here, explanation is given on the assumption that association between each of the three metadata items "Customer Name", "Address", and "Billing Name" and the text block has been performed along the flow in FIG. 6 of the first embodiment and the state of the UI screen shown in FIG. 14 is brought about.

On the UI screen in FIG. 14, at the top left of the text block 501 within the page image 402, a label 1401 indicating the number of metadata items (here, "two") with which the text block is associated is attached. This label is displayed at the timing at which the same text block is associated with a plurality of metadata items (that is, at the point in time at which the number of metadata items becomes two or more), but this is not limited and it may also be possible to display

the label at the timing at which the text block is associated with one of metadata items. Then, here, the text block **501** is the state of being colored in the default color (here, gray color) in a case where association with a plurality of metadata items is performed. In contrast to this, a text block **1402** associated with only one metadata item “Address” is colored in the blue color indicated by the corresponding item color area **511b**.

It is assumed that one of the display fields **510a** to **510c** of each metadata item within the Property pane **411** is selected by a user (touch operation or the like with a finger) in a case where the UI screen is in the state shown in FIG. **14**. At **S1301**, the operation event, such as the touch operation or the like by a user, is detected. Here, it is assumed that the operation event for the display field **510c** of “Billing Name” is detected. At **S1302** that follows, whether the text block associated with the metadata item selected by the user is also associated with another metadata item is determined. In a case where the determination results are “No”, this processing is completed. On the other hand, in a case where the determination results are “Yes”, the processing advances to **S1303**. Here, the text block **501** is associated with the metadata item “Billing Name” selected by the user and further, the text block **501** is also associated with the metadata item “Customer Name”. Consequently, the determination results in this case is “Yes” and the processing advances to **S1303** as a result.

At **S1303**, the text block associated with the selected metadata item is colored in the same color as the color of the item color area of the selected metadata item. Here, the color of the text block **501** changes from the gray color, which is the default color, to the yellow color indicated by the item color area **511c** within the display field of the metadata item “Billing Name”. The UI screen shown in FIG. **15** shows the state where the color of the text block **501** has changed from the gray color to the yellow color accompanying the selection of the metadata item “Billing Name”.

At next **S1304**, a button for cancelling the association between the selected metadata item and the text block is displayed. On the UI screen in FIG. **15**, a “x” mark button **1501** that appears at the top right of the text block **501** indicates the cancel button. At **S1305** that follows, whether or not the touch operation or the like is performed to the cancel button is determined. In a case where the operation event, such as the touch operation to the cancel button, is detected, the processing advances to **S1306** and in a case where no operation event is detected, this processing is exited.

At **S1306**, the association between the selected metadata item and the text block is cancelled and the label indicating the number of metadata items currently associated is updated. Specifically, as a result of that the association with the selected metadata item is cancelled, “one” is subtracted from the number of metadata items indicated by the label. In the example in FIG. **15**, the numerical value of the label **1401** changes from “two” to “one”. Further, accompanying this, the display field corresponding to the selected metadata item is initialized and the blank state is brought about. Here, the selected metadata item is “Billing Name”, and therefore, the corresponding display field **510c** is initialized.

The above is the contents of the UI screen control processing in the client application **351** according to the present embodiment.

As above, according to the present embodiment, even in a case where the same text block is associated with a plurality of setting items (slave items), it is possible for a

user to grasp the correspondence relationship between a slave item and a text block both accurately and easily.

Other Embodiments

Embodiment(s) of the present disclosure can also be realized by a computer of a system or apparatus that reads out and executes computer executable instructions (e.g., one or more programs) recorded on a storage medium (which may also be referred to more fully as a ‘non-transitory computer-readable storage medium’) to perform the functions of one or more of the above-described embodiment(s) and/or that includes one or more circuits (e.g., application specific integrated circuit (ASIC)) for performing the functions of one or more of the above-described embodiment(s), and by a method performed by the computer of the system or apparatus by, for example, reading out and executing the computer executable instructions from the storage medium to perform the functions of one or more of the above-described embodiment(s) and/or controlling the one or more circuits to perform the functions of one or more of the above-described embodiment(s). The computer may comprise one or more processors (e.g., central processing unit (CPU), micro processing unit (MPU)) and may include a network of separate computers or separate processors to read out and execute the computer executable instructions. The computer executable instructions may be provided to the computer, for example, from a network or the storage medium. The storage medium may include, for example, one or more of a hard disk, a random-access memory (RAM), a read only memory (ROM), a storage of distributed computing systems, an optical disk (such as a compact disc (CD), digital versatile disc (DVD), or Blu-ray Disc (BD)TM), a flash memory device, a memory card, and the like.

According to the technique of the present disclosure, on a UI screen having a preview pane and a property pane, it is possible for a user to easily grasp a correspondence relationship between a text block and a setting item.

While the present disclosure has been described with reference to exemplary embodiments, it is to be understood that the disclosure is not limited to the disclosed exemplary embodiments. The scope of the following claims is to be accorded the broadest interpretation so as to encompass all such modifications and equivalent structures and functions.

This application claims the benefit of Japanese Patent Applications No. 2020-007518 filed Jan. 21, 2020, and No. 2020-031689 filed Feb. 27, 2020, which are hereby incorporated by reference wherein in their entirety.

What is claimed is:

1. An image processing system that computerizes a document, comprising:
 - a memory that stores a program; and
 - a processor that executes the program to perform:
 - displaying a user interface screen for setting a property to a scanned image obtained by scanning the document; and
 - controlling a display on the user interface screen, wherein
 - on the user interface screen, at least a preview pane that is an area preview-displaying the scanned image and a property pane that is an area to which a setting value of each setting item of the property is input exist, and
 - wherein at least a part of a field of a setting item displayed in the property pane and a text block corresponding to the setting item in the scanned image preview-displayed in the preview pane are colored with a same color or similar colors.

15

2. The image processing system according to claim 1, wherein the controlling:
 - performs coloring the at least a part of the field of the setting item with a color allocated to the setting item; and
 - performs coloring, in a case where a user selects one of text blocks in the scanned image preview-displayed in the preview pane in a state where one of setting items is selected in the property pane, the selected one text block with a color that is same as or similar to the color allocated to the setting item in the selected state.
3. The image processing system according to claim 1, wherein the controlling performs the coloring of the at least a part of the field of the setting item displayed in the property pane at timing at which an operation event for selecting the setting item displayed in the property pane is detected.
4. The image processing system according to claim 1, wherein the controlling performs the coloring of the at least a part of the field of the setting item displayed in the property pane at the same timing as the coloring of the text block in the scanned image preview-displayed in the preview pane.
5. The image processing system according to claim 1, wherein the at least part of the display field is a color area provided within the field.
6. The image processing system according to claim 2, wherein the controlling allocates a color not similar to a character color or a background color of the text block included in the scanned image to the setting item.
7. The image processing system according to claim 2, wherein the controlling allocates a specific color to the setting item based on item color information defining a plurality of allocatable colors.
8. The image processing system according to claim 7, wherein in the item color information, a color in accordance with an order in a plurality of setting items is associated, respectively and the controlling allocates a color corresponding to an order of a setting item to the setting item by referring to the item color information.
9. The image processing system according to claim 7, wherein the controlling performs the coloring by changing, in a case where a color allocated in accordance with the item color information is similar to a character color or a background color of a text block selected by a user, the allocated color to a color that is not similar.
10. The image processing system according to claim 2, wherein the controlling specifies a chromatic color that appears frequently among character colors or background colors of text blocks included in the scanned image and allocates a color that is not similar to the chromatic color to the setting item.
11. The image processing system according to claim 10, wherein

16

- the controlling allocates a color located at a distant position in a hue circle with the chromatic color being taken as a reference to the setting item.
12. The image processing system according to claim 10, wherein the controlling allocates a color that is not similar to the chromatic color among a plurality of candidate colors determined in advance to the setting item.
13. The image processing system according to claim 1, wherein the controlling displays, in a case where a text block of the scanned image preview-displayed in the preview pane is associated with a plurality of setting item displayed in the property pane, a label indicating a number of the plurality of setting items for the text block.
14. The image processing system according to claim 13, wherein the controlling displays the label when text block of the scanned image preview-displayed in the preview pane is associated with the plurality of setting items displayed in the property pane.
15. The image processing system according to claim 13, wherein the controlling:
 - displays a button for cancelling association in a case where a text block associated with a setting item selected by a user among setting items displayed in the property pane is also associated with another setting item; and
 - reduces a number of setting items indicated by the label in a case where an operation event of a selection operation for the cancel button is detected.
16. A control method of an image processing system that computerizes a document, the image processing system comprises a display for displaying a user interface screen for setting a property to a scanned image obtained by scanning the document and a controller for controlling the display on the user interface screen, wherein on the user interface screen, at least a preview pane that is an area preview-displaying the scanned image and a property pane that is an area to which a setting value of each setting item of the property is input exist, and wherein at least a part of a field of a setting item displayed in the property pane and a text block corresponding to the setting item in the scanned image preview-displayed in the preview pane are colored with a same color or similar colors.
17. A non-transitory computer readable storage medium storing a program for causing a computer to perform:
 - displaying a user interface screen for setting a property to a scanned image obtained by scanning a document; wherein
 - on the user interface screen, at least a preview pane that is an area preview-displaying the scanned image and a property pane that is an area to which a setting value of each setting item of the property is input exist; and
 - controlling to perform coloring at least a part of a field of a setting item displayed in the property pane and a text block corresponding to the setting item in the scanned image preview-displayed in the preview pane with a same color or similar colors.
