A shared beamformer flexibly allocates beams among clusters of beams produced by phased array antenna apertures that are deployed on a satellite (or other type of platform). By sharing the beamformer among the beam clusters, if one beam cluster is not providing useful coverage, the beams may be reallocated to one or more other beam clusters that are providing useful coverage. To share the beamformer among the beam clusters, a selector network is used to select which particular beam cluster (or clusters) is used for producing one or more narrow beams that are constrained to the coverage area of the beam cluster (or clusters).
A SHARED PHASED ARRAY CLUSTER BEAMFORMER

CROSS REFERENCE TO RELATED APPLICATIONS

[0001] This application is a Continuation-in-part of prior U.S. application serial number 11/117,381, filed on April 29, 2005.

STATEMENT AS TO RIGHTS TO INVENTIONS MADE UNDER FEDERALLY SPONSORED RESEARCH OR DEVELOPMENT

[0002] Not Applicable.

TECHNICAL FIELD

[0003] This disclosure relates to phased array antenna systems and, more particularly, to beamformers for phased array antenna systems.

BACKGROUND

[0004] With the advances in wireless technology, satellites such as low earth orbit satellites are used in telecommunication systems to establish communication links across long distances. To produce these links, phased array antennas have been incorporated into some satellites as well as mobile and stationary ground stations. A phased array antenna typically has one or more apertures that are assembled from a large number of radiating elements, such as slots or dipoles. By individually controlling a phase shift and attenuation that is applied to each element, predictable beams may be formed and accurately pointed in particular directions. Each aperture is assigned a fixed number of beams and each beam may be pointed in a direction to establish a communication link. For example, a multi — aperture satellite may include four phased array antenna apertures and twelve beams are assigned to each aperture (for a total of forty-eight beams associated with the satellite). Thus, each of the phased array antenna apertures may point its twelve beams in various directions to establish links. However, during particular times and at particular locations in
the satellite's orbit, one or more of the apertures may be positioned in such an orientation as
to not provide useful coverage. Similarly, one or more of the apertures may operate with
different frequencies and/or polarizations. Due to these different electromagnetic
operating characteristics, useful coverage may also not be provided at all times. Due to
these periods of poor coverage, the beams assigned to one or more of the phased array
apertures are wasted since they can not establish communication links.

**SUMMARY OF THE DISCLOSURE**

[0005] The subject matter disclosed herein solves these problems by providing a
beamformer that flexibly allocates beams among clusters of beams produced by phased
array antenna apertures that are deployed on a satellite (or other type of platform). By
sharing the beamformer among the beam clusters, if one beam cluster is not providing
useful coverage (due to light traffic volume, signal frequency, signal polarization, etc.), the
beams may be reallocated to one or more other beam clusters that are providing useful
coverage. To share the beamformer among the beam clusters, a selector network (e.g., one
or more switches) is used to select which particular beam cluster (or clusters) is used for
producing one or more narrow beams that are constrained to the coverage area of the beam
cluster (or clusters). Such systems and methods can be applied in receive mode, transmit
mode, or both of the phased array antenna.

[0006] In accordance with an aspect of the disclosure, a phased array antenna system
includes a beamformer that produces an antenna beam from two or more electromagnetic
signals received from two or more phased array antenna elements. The phased array
antenna system also includes a selector that provides the antenna beam to another
beamformer that produces a second antenna beam. The coverage provided by the second
antenna beam is partially constrained by the coverage provided by the first antenna beam.

[0007] In one embodiment, the pointing direction of the second antenna beam may be
partially constrained by the beamwidth of the first antenna beam. The first antenna beam may have a larger beamwidth than the second antenna beam. The phased array antenna elements may be included in the same phased array aperture. The phased array antenna elements may be included in different phased array apertures. The first beamformer may include a phase shifter that adjusts the phase of a signal associated with one or more of the received signals. The first beamformer may include an attenuator that attenuates a signal associated with one or more of the received signals. The selector may include a two-way switch, a semiconductor switch, a mechanical switch, a ferrite switch, an optical switch, a digital switch, or other type of switch. The selector may execute instructions to provide the antenna beam to the other beamformer. Either or both of the beamformers and the selector may be included in an integrated package.

[0008] In accordance with another aspect of the disclosure, a phased array antenna system may comprise a plurality of sets of antenna elements configured to transmit, receive, or both, a set of signals. The phased array antenna system may also comprise a first set of antenna elements associated with a first aperture and coupled to a first beamforming stage configured to produce at least one first antenna beam and a second set of antenna elements associated with a second aperture and coupled to a second beamforming stage configured to produce at least one second antenna beam. A selector is coupled to the first beamforming stage and the second beamforming stage and is configured to allocate antenna beams from the at least one first antenna beam and the at least one second antenna beam to a third beamforming stage. The third beamforming stage is configured to generate at least one third antenna beam, wherein coverage provided by the at least one third antenna beam is at least partially constrained by the coverage provided by the at least one first antenna beam, or the at least one second antenna beam or both.

[0009] In one embodiment, the pointing direction of the at least one second antenna beam may be partially constrained by the beamwidth of the at least one first antenna beam.
The at least one first antenna beam may have a larger beamwidth than the at least one second antenna beam. The phased array antenna elements may be included in the same or different phased array apertures. Also, the selector may include a switch.

[0010] In accordance with another aspect of the disclosure, a method of producing electromagnetic beams includes receiving electromagnetic signals from two phased array antenna elements and beamforming the signals to produce at least one antenna beam. The method also includes selecting to beamform the antenna beam to produce at least another antenna beam, in which coverage provided by the second antenna beam is partially constrained by the coverage provided by the first antenna beam.

[0011] In one embodiment, the method may also include beamforming the first antenna beam to produce the second antenna beam.

[0012] In accordance with another aspect of the disclosure, a method of producing electromagnetic beams includes receiving electromagnetic signals from two phased array antenna elements and beamforming the signals to produce at least one antenna beam. The method also includes beamforming the antenna beam to produce at least a second antenna beam, in which coverage provided by the second antenna beam is partially constrained by the coverage provided by the first antenna beam. The method also includes selecting the first antenna beam from other produced beams.

[0013] In one embodiment, the method may also include constraining the selecting of produced beams to a particular number of beams.

[0014] In accordance with another aspect of the disclosure, a phased array antenna system may comprise a plurality of sets of antenna elements configured to transmit, receive, or both, a set of signals. The phased array antenna system may comprise a first set of antenna elements associated with a first aperture and coupled to a first beamformer configured to produce at least one first antenna beam. A first selector may be coupled to
the first beamformer and coupled to a second beamformer, wherein the second beamformer is configured to produce at least one second antenna beam that is partially constrained by the at least one first antenna beam. A second set of antenna elements is associated with a second aperture and coupled to a third beamformer configured to produce at least one third antenna beam. A second selector may be coupled to the third beamformer and coupled to a fourth beamformer, wherein the fourth beamformer is configured to produce at least one fourth antenna beam that is partially constrained by the at least one third antenna beam. A final selector is coupled to the second beamformer and the fourth beamformer and may be configured to allocate antenna beams from the at least one second antenna beam and the at least one fourth antenna beam. And a final beamforming stage may be coupled to the final selector and configured to generate at least one final antenna beam, wherein coverage provided by the at least one final antenna beam is at least partially constrained by the coverage provided by the at least one second antenna beam, or by the at least one fourth antenna beam or both.

Additional advantages and aspects of the present disclosure will become readily apparent to those skilled in the art from the following detailed description, wherein embodiments of the present invention are shown and described, simply by way of illustration of the best mode contemplated for practicing the present invention. As will be described, the present disclosure is capable of other and different embodiments, and its several details are susceptible of modification in various obvious respects, all without departing from the spirit of the present disclosure. Accordingly, the drawings and description are to be regarded as illustrative in nature, and not as limitative.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a diagrammatic view of a satellite that includes a phased array antenna system that is configured to produce multiple transmission and/or reception beams.
FIG. 2 is a diagrammatic view of dedicated phased array beamformers for two apertures included in the phased array antenna system shown in FIG. 1.

FIG. 3 is a diagrammatic view of one dedicated phased array beamformer for one of the apertures shown in FIG. 2.

FIG. 4 is a diagrammatic view of a selector network that shares a beamformer to allocate beams between the two apertures included in the phased array antenna system shown in FIG. 1.

FIG. 5 is a diagrammatic view of a phased array antenna system that produces multiple allocatable beams with less hardware than the phased array antenna system shown in FIG. 3 that includes dedicated beamformers.

FIG. 6 is a diagrammatic view of another embodiment of a phased array antenna system that shares beamformers to produce multiple beams that are allocated in groups.

FIG. 7 presents a table that compares the hardware components needed to implement a phased array antenna system with dedicated beamformers and the hardware components needed to implement a phased array antenna system that shares beamformers.

FIG. 8 is an illustrative view of coverage provided by two beam clusters.

FIG. 9 is a block diagram of an exemplary shared cluster beamformer.

FIG. 10 is a block diagram of an exemplary cluster-former that is implemented in the shared cluster beamformers shown in FIG. 9.

FIG. 11 is a block diagram of another exemplary shared cluster beamformer.

**DETAILED DESCRIPTION OF THE EMBODIMENTS**

Referring to FIG 1, a satellite 10 is shown in orbit and includes a phased array antenna system 12 that is capable of producing multiple beams. Phased array antenna system 12 includes four apertures 14, 16, 18 and 20. In this representation, apertures 18 and 20 are shown producing four distinct beams 22, 24, 26, and 28. Each of these beams
may be used for transmitting and/or receiving electromagnetic signals to and from locations respectively covered by phased array antenna system 12. For example, beam 22 may be used to receive an electromagnetic signal (e.g., a radio frequency (RF) signal, etc.) that is transmitted from a ground station 30 that is covered by beam 22. To receive the electromagnetic signal on beam 22, phased array antenna system 12 or a portion of the phased array antenna system (e.g., aperture 18) is designed to operate at one or more frequencies (e.g., C-band, Ku-band, etc.) within the electromagnetic spectrum in which ground station 30 transmits. Additionally, phased array antenna system 12 may be designed to receive electromagnetic signals with one or more polarizations. For example, phased array antenna system 12 or a portion of the phased array antenna system (e.g., aperture 18) may be designed to operate with polarizations such as linear polarizations (e.g., vertical, horizontal, etc.), circular polarization (e.g., right hand circular, left hand circular, etc.), elliptical polarization, or other similar electromagnetic polarization.

[0028] Continuing with the example, after receiving the electromagnetic signal over beam 22, the signal may be processed (e.g., amplified, placed in another frequency band, etc.) by hardware onboard satellite 10. For example, a C-band, vertically polarized signal may be received from ground station 30 over beam 22. Once received, circuitry in a payload module 32 (and/or circuitry located near one or more of the radiating elements) may process the signal for transmission to another location that is covered by satellite 10. For example, the signal may be amplified, mixed to a frequency within the Ku-band, and transmitted with a horizontal polarization. In this scenario, the processed signal is transmitted over beam 28 to a mobile station 34 (e.g., a car, a truck, etc.).

[0029] Referring to FIG 2, a block diagram representing a portion of payload module 32 and apertures 14 and 16 are shown. Each aperture includes a number of antenna elements that in aggregate form the respective aperture. For illustrative purposes, only three elements are shown in aperture 14 and aperture 16. In particular, aperture 14 includes
antenna elements 36, 38 and 40 while aperture 16 includes antenna elements 42, 44 and 46.

In this example, both apertures 14 and 16 are configured to receive electromagnetic signals. However, typically platforms such as satellite 10 include phased array antennas for transmitting and receiving. For example, one phased array antenna is configured to transmit at a particular frequency band (e.g., Ku, Ka, etc.) and polarization (e.g., linear polarization, etc.) and a complementary phased array antenna is configured to receive at a different frequency and orthogonal polarization. Each of the antenna elements (e.g., elements 36—46) may be implemented with identical or dissimilar antenna designs (e.g., dipoles, patches, helices, etc.) that are well known to a person of skill in the art of antenna design and antenna system design. Each antenna element 36—46 is respectively connected to a low noise amplifier 48, 50, 52, 54, 56, 58 that conditions the received signal prior to providing it to payload module 32.

[0030] In this example payload module 32 includes two conventional four-beam beamformers 60, 62 that each produce four beams from the electromagnetic signals respectively received by apertures 14 and 16. These eight beams may be steered in angular directions to cover particular geographic locations and the beam coverage areas may or may not overlap. For example, the four beams associated with four-beam beamformer 60 may be steered to locations as illustrated in FIG 1. Typically a platform such as satellite 10 may be capable of producing more than eight beams. For example, satellite 10 may be capable of producing thirty-two, forty-eight, or more beams. However, for ease of illustration only eight beams are described, although the number of beamformers and beamformer components is scalable to produce additional beams for transmission and/or reception of electromagnetic signals.

[0031] To produce the eight beams, respective conductors 64, 66, 68, 70, 72 and 74 (e.g., conducting traces, RF cables, waveguides, etc.) provide the signals from low noise amplifiers 48—58 to conventional four-beam beamformers 60, 62. In some arrangements,
the signals may be adjusted prior to being received at the beamformers. For example, the
signals may be mixed to an intermediate frequency (IF) prior to being processed by the
beamformers. The signals may also be converted into another portion of the
electromagnetic spectrum for processing by the beamformers. For example, the signals
from low noise amplifiers 48 —58 may be converted into optical signals prior to being
provided to beamformers 60 and 62.

[0032] Referring also to FIG 3, a block diagram of four-beam beamformer 60, which is
dedicated to aperture 14, is shown. As mentioned above, four beams are produced from
signals provided by the antenna elements in aperture 14. Each respective beam is produced
by an individual beamformer 76, 78, 80, 82. Since each of the four beamformers 76, 78, 80,
82 have identical components, a description of one beamformer (e.g., beamformer 76) is
provided to commonly describe all four of the beamformers. In general, to produce a
reception beam, phase shifts (and/or in some situations, attenuations) are respectively
applied to the signals received at the phased array antenna elements 36, 38, 40. By
adjusting these phase shifts (and/or attenuations) the phase front of the aggregated antenna
elements is steered to a particular angular direction.

[0033] Using phased array antenna element 36 to demonstrate the processing by
four-beam beamformer 60; low noise amplifier 48 provides the received electromagnetic
signal conductor 64 to a 2-way power divider 84 that is included in payload module 32. In
this embodiment, 2-way power divider 84 splits the received signal and provides the signal
to 2-way power divider 86 over conductor 88. The signal is also provided to 2-way power
divider 90 over conductor 92. By dividing the signal four-ways, each signal is used to
 produce the four independent beams in beamformers 76, 78, 80, 82. In other scenarios the
signals may be further divided to produce more than four beams (e.g., eight beams, sixteen
beams, etc.).

[0034] Conductors 94, 96, 98 and 100 respectively provide the four split signals to
Similarly signals from antenna elements 38 and 40 are split and sent to each of the beamformers. Focusing on beamformer 76, three phase shifters/attenuators 102, 104, 106 receive the signals from antenna elements 36, 38, and 40. In particular phase shifter/attenuator 102 is provided signals from antenna element 36 via conductor 94. Similarly, shifter/attenuator 104 is provided signals from antenna element 38 and shifter/attenuator 106 is provided signals from antenna element 40. Each phase shifter/attenuator 102, 104, 106 applies a phase shift to the respectively received signal. For example, phase shifter/attenuator 102 may apply a 0° phase shift while phase shifter/attenuators 104 and 106 respectively apply phase shifts of 22.5° and 45°. In a similar manner phase shifts may be applied to the signals processed by beamformers 78, 80, and 82 for steering the corresponding beams. In some scenarios, one or more of the phase shifter/attenuators in beamformers 76, 78, 80, and 82 may apply an attenuation or a phase shift and an attenuation to steer and/or shape the beams.

Still focusing on beamformer 76, once the phase shift(s) (and attenuation(s)) is applied, each phase-shifted signal is provided to a three-way combiner 108 included in the beamformer. Combiner 108 produces a beam (i.e., beam 1) by combining the phased shifted signals from each antenna element. For example, three-way combiner 108 may combine signals from antenna elements 36, 38, 40 to produce and steer a beam in a direction based on the relative phase shift of each path. Similarly, three-way combiners 110, 112, 114 in respective beamformers 78, 80, and 82 may receive signals from the each antenna element that have been phase shifted by amounts to produce and steer the other three beams (i.e., beams 2, 3, and 4).

This figure shows the components included in four-beam beamformer 60, which is dedicated to antenna aperture 14. Similarly, antenna apertures 16, 18, and 20 are connected to dedicated beamformers that accordingly divide received signals and apply one or more phase shifts (and/or attenuations). By implementing these 'dedicated
beamformers, a fixed number of beams are allocated to each aperture. In this example, the allocation of the four beams (produced by 3-way combiners 108, 110, 112, and 114) are fixed. Thereby, if phased array antenna aperture 16 is oriented such that it can provide better coverage, beams can not be reallocated from phased array antenna aperture 14 to aperture 16. Furthermore, if aperture 14 is at an angular position that provides no useful coverage, the beams allocated to aperture 14 are wasted. For example, antenna aperture 14 may be facing westward and phased array antenna 16 may be facing eastward while satellite 10 is in low earth orbit. At a particular time of the day, signal traffic may be dominant in the west in comparison to the east. In such a scenario, it may be advantageous to allocate more beams to the westward facing phased array antenna aperture 14 than the eastward facing phased array antenna aperture 16. However, since the beam allocation is fixed, appropriate westward coverage may not be provided and the eastward pointing beams may be underutilized. In other scenarios, rather than orientation, fixed beam allocation may provide inappropriate coverage based on transmit and/or reception beam parameters (e.g., frequency, polarization, etc.).

[0037] Additionally, by dedicating a beamformer to underutilized antenna apertures or antenna elements (e.g., due to antenna pointing, operating frequency, polarization, etc.), hardware components that are currently of little use occupy valuable real estate on satellite 10. Furthermore, these hardware components add weight to the satellite 10 and increase the cost to produce and operate (e.g., due to power consumption) satellite 10.

[0038] Referring to FIG 4, a portion of payload module 32 is shown to include one four-beam beamformer 116 that is shared among antenna elements of phased array antenna apertures 14 and 16. By sharing beamformer 116, the number of hardware components is reduced, which correspondingly reduces the cost and weight of payload module 32. Furthermore, by sharing beamformer 116 among antenna elements, the pool of beams produced by the beamformer may be flexibly allocated among the phased array antenna
apertures depending upon the orientation of satellite 10 (or other type of platform), signal traffic volume, or beam parameter (e.g., frequency, polarization, etc.). Using the example described above, to provide appropriate westward coverage, more beams may be allocated to the westward facing aperture by re-allocating beams currently assigned to the eastward facing aperture. At a later time some or all of the beams may be returned for eastward coverage by re-allocating the beams to the eastward facing phased array antenna aperture.

[0039] In this example, apertures 14 and 16 share four-beam beamformer 116, which produces four steerable beams (i.e., Beam 1, Beam 2, Beam 3, Beam 4) that may be allocated among the apertures. Similar to FIG 2, apertures 14 and 16 respectively include three array elements (i.e., antenna elements 36, 38, 40 and antenna elements 42, 44, 46) for illustrative purposes. Low noise amplifiers 48—58 respectively connect to antenna elements 36—46 and condition received electromagnetic signals.

[0040] To share four-beam beamformer 116 between apertures 14 and 16, a selector network 118 selects which signals are provided to the four-beam beamformer. The selector network 118 can take a variety of forms, such as selector network 118A in FIG 5 or selector network 118B in FIG 6. By being capable to select signals from antenna elements 36 - 40, all four beams may be allocated to provide coverage for aperture 14. At a different time, or when satellite 10 is in a different position, selector network 118 may be configured to beamform signals received by antenna element 42—46 to provide coverage for aperture 16. In still another example, two beams (e.g., beam 1 and beam 2) may be allocated to aperture 14 and the other two beams (e.g., beam 3 and beam 4) may be allocated to aperture 16. Along with providing flexibility to allocate beams among the phased array antenna apertures, beamformer sharing reduces the number of beamformer components in payload module 32. By reducing the number of components, the mass of payload module 32 along with the cost are correspondingly reduced.

[0041] Referring to FIG. 5, components included in selector network 11SA and
four-beam beamformer 116 are shown that allocate beams between aperture 14 and aperture 16. In this embodiment, beamformer 116 takes the form of beamformer 116A. Both apertures 14 and 16 include components (e.g., antenna elements 36—46 and low noise amplifiers 48–58) that are shown in FIG 4. Conductors 120, 122, 124, 126, 128, 130 connect the low noise amplifiers to selector network 118A. In particular, array element 36 is connected to a 4-way power divider 132, array element 38 is connected to a 4-way power divider 134, array element 40 is connected to 4-way power divider 136. Regarding aperture 16, array element 42 is connected to another 4-way power divider 138, array element 44 is connected to 4-way power divider 140, and array element 46 is connected to 4-way power divider 142. Signals from each antenna element are four-way divided so that each signal may be selected for phasing shifting (and/or attenuating) to produce each of the four beams.

[0042] Selector network 118A is used to select which antenna elements provide signals to produce the four beams. By selecting from among antenna elements 36, 38, 40, 42, 44, and 46, the four beams may be allocated to either one or more of the phased array antenna apertures 14, 16. For example, all four beams may be allocated to aperture 14 during periods of heavy communication traffic in the area covered by aperture 14. At other times, one, two, three, or four of the beams may be allocated to aperture 16 to increase link capacity for the area covered by phased array antenna 16.

[0043] In this example, selector network 118A includes twelve 2-way selectors 144, 146, 148, 150, 152, 154, 156, 158, 160, 162, 164 and 166. By including the 2-way selectors, signals from each of the antenna elements may be selected to produce one or more of the four beams. To produce the four beams, four-beam beamformer 116A includes four single-beam beamformers 168, 170, 172, 174. To select signals from antenna elements, 2-way selectors 144, 146, 148, and 150 are assigned to select between antenna elements 36 and 42. Antenna elements 38 and 44 are assigned to 2-way selectors 152, 154,
156 and 158 while antenna elements 40 and 46 are assigned to 2-way selectors 160, 162, 164, and 166.

[0044] By controlling the 2-way selectors, signals received from all or a subset of the antenna elements are beamformed to produce the four beams. Typically, the 2-way selectors connected to a common beamformer are placed in the same position. For example, 2-way selectors 144, 152 and 160 (which are all connected to beamformer 168) are placed in the same position so that signals from the same aperture are provided to beamformer 168. Similarly, 2-way selectors 146, 154, 162 are typically placed in the same position and 2-way selectors 148, 156, 164 are also placed in the same position. Also, 2-way selectors 150, 158, and 166 are typically placed in the same position to beamform signals from the same aperture. For example, 2-way selectors 144 - 166 may be placed in appropriate positions to beamform signals from antenna elements in aperture 14. By selecting signals from the aperture 14, all four beams are allocated to provide coverage for aperture 14. At a different time, or when satellite 10 is in a different position, 2-way selectors 144 — 166 may be placed in appropriate positions to beamform signals received by antenna element 42, 44, 46. By selecting signals from these antenna elements in aperture 16, all four beams are now allocated to provide coverage for aperture 16. In still another example, one beam (e.g., beam 1) may be allocated to aperture 14 and the other three beams (e.g., beam 2, 3 and 4) may be allocated to aperture 16.

[0045] Similar to beamformers 16, 78, 80, 82 shown in FIG 3, beamformers 168, 170, 172, and 174 include phase shifter/attenuators that phase shift (and/or attenuate) the signals. After applying a phase shift and/or an attenuation, the signals are provided to corresponding 3-way combiners that are included in each beamformer 168, 170, 172, and 174. By combining the signals from the phase shifter/attenuators, the four 3-way combiners respectively produce beams 1, 2, 3 and 4.

[0046] In this arrangement, selector network 118A includes 2-way selectors to
respectively share the beamformers 168—174 among the antenna elements in phased array antenna apertures 14 and 16. However, in other arrangements one or more of the selectors may be a 3-way, 4-way, or N-way selectors (where N is any integer number) to allow for more antenna apertures to share the beamformers. Various techniques may be used to implement the 2-way, 3-way, or N-way selectors. For example, various types of switches may provide the selection function. Along with mechanical switches, other switching techniques known to one skilled in the art of telecommunications and electronics may be incorporated. For example, semiconductor switches, ferrite switches, switches fabricated with micro-electro-mechanical systems (MEMS), digital switches, etc. The selection function may also be provided by one or more processors (e.g., digital signal processors, microprocessors, etc.) that execute appropriate instructions. In this example, the 2-way selectors are used to select from the electromagnetic signals received by antenna elements 36—46. However, besides selecting from the received electromagnetic signals (e.g., RF microwave signals, RF milliwave signals, etc.), the signals collected at the antenna elements may be converted prior to being provided to the selector networks. For example, the signals may be converted into optical signals and provided to optical switches included in the selector networks.

[0047] In this example each selector is a single 2-way selector, however in some arrangements one or more of the selectors may be implemented by a network of multiple switches or a network of other types of selector devices. Also, beamformers 168—174 are implemented with discrete components (e.g., phase shift/attenuators, 3-way combiners, etc.). In other arrangements, the discrete components may be integrated into a single package. For example, all of the components included in beamformer 168 may be integrated into a single package (e.g., an optical-electronic integrated package, an RF integrated package, etc.) or other type of integrated assembly. Similarly, the selector network 118 (e.g., selector network 118A or 118B) or a portion of the selector network may be integrated into a single package.
Along with providing flexibility to allocate beams among the phased array antennas, beamformer sharing reduces the number of components in payload module 32. By comparing the four shared beamformers 168—174 shown in FIG 5 to the eight dedicated beamformers (four of the eight are shown in FIG. 3), the shared beamformers include less hardware components. By reducing the number of components, the mass of payload module 32 along with the cost are correspondingly reduced.

Referring to FIG. 6, beamformers may be shared such that the beams allocated to a phased array antenna aperture are constrained to a group size. For example, an aperture may be constrained such that beams are allocated in groups of two. So, using this constraint, e.g., zero, two, or four beams may be allocated to each of the phased array antenna apertures. To provide this grouping constraint, in this example, signal dividers (e.g., power dividers) are included in the selector network, here selector network 118B. In particular, a signal divider is respectively inserted between each selector (in selector network 118B) and each phase shifter/attenuator (in four—beam beamformer 116A).

To constrain phased array antenna aperture 14 and 16 to groups of two beams, payload module 32 includes 2-way power dividers that connect the selector network 118B to the phase shifter/attenuators included the beamformers 168, 170, 172, and 174. In particular, 2-way power dividers 178, 180, 182, 184, 186 and 188 respectively connect 2-way selectors 190, 192, 194, 196, 198, 200 to the phase shift/attenuators included in beamformers 168, 170, 172, and 174. To expand the constraint, by dividing the selected signal N-ways, each phased array antenna aperture is constrained to groups of N beams (e.g., ON, N, 2N, 3N, etc.).

By including 2-way power dividers 178—188, two two-beam groups are allocated between aperture 14 and aperture 16. For example, say both two-beam groups (for a total of all four beams) are allocated to aperture 14. In this scenario, signals received by antenna elements 36, 38, and 40 are provided (via low noise amplifiers 48, 50, 52) to
respective 2-way power dividers 202, 204, and 206. The signals are split by the power dividers and are provided to 2-way selectors 190 - 200. By placing 2-way selectors 190 - 200 in appropriate selection positions, the split signals are provided to two 2-way power dividers 178 — 188 and the corresponding phase shifters/attenuators of beamformers 168, 170, 172 and 174. Thus, two groups of two beams (i.e., beam 1, beam 2, beam 3, and beam 4) are allocated to aperture 14. In a similar manner, by placing 2-way selectors 190 — 200 in appropriate selection positions, signals received at antenna element 42, 44, and 46 (and sent via low noise amplifiers 54, 56 58 and 2-way power dividers 208, 210, 212) are provided to 2-way power dividers 178 — 188 and then to the phase shifters/attenuators in beamformers 168, 170, 172, and 174. Once the signals are appropriately phase shifted and optionally attenuated, the signals are provided to the 3-way combiners to produce and allocate all four beams (i.e., beams 1, 2, 3, and 4) to aperture 16.

[0052] Selector network 118A shown in FIG 5 allowed four beams to be individually allocated between phased array antenna apertures 14 and 16. For example, all four beams could be allocated to aperture 14 or to aperture 16. Alternately, one, two, or three beams maybe allocated to aperture 14 or aperture 16 (so long as the sum of the allocated beams does not exceed four). In contrast, selector network 118B in FIG 6 constrains beam allocation to particular groups of beams. As shown in FIG 6, network selector 118B includes 2-way power dividers 178 — 188 to constraint beam allocation to groups of two. For example, four beams (two groups of two beams) may be allocated to aperture 14 or to aperture 16. In another example, one group of two beams (e.g., beams 1 and 2) may be allocated to aperture 14 and another group of two beams (e.g., beams 3 and 4) may be allocated to aperture 16. Generally, selector network 118 may be extended to allocate more individual beams or groups of beams. For example, from a pool of N beams (e.g., sixteen beams, thirty-two beams, forty-eight beams, etc.), a selector network may be implemented such that the N beams are flexibly allocated among phased array antenna apertures. For example, the N beams may be evenly or unevenly distributed among the apertures. During
particular time periods more beams may be allocated to a particular aperture to provide needed coverage for increased signal traffic. Along with allocating beams individually, beams may be allocated in groups that may or may not be constrained to one group size. For example, groups of one, two, three, or four beams may be designated for allocation. Furthermore, multiple group sizes may be implemented that may be similar or dissimilar in size. Along with constraining beam groups to a particular number, grouping may also be constrained by one or more other parameters. For example, beams may be grouped by frequency band (e.g., C-band, Ku-band, etc.), polarization (e.g., linear vertical, linear horizontal, right hand circular, left hand circular, elliptical, etc.), or one or more other parameters.

[0053] Referring to FIG. 7, a table 214 is shown that compares the approximate number of components included in an antenna system using dedicated beamformers (e.g., beamformers 76, 78, 80, 82 shown in FIG 3) to the number of components included in an antenna system using shared beamformers (e.g., beamformers 168, 170, 172 and 174 shown in FIG 5). To compare the number of components, variables are respectively assigned to parameters associated with the components. The letter "L" is defined as the number of phased array antenna apertures and the letter "M" is defined as the number of elements in each phased array antenna aperture. Continuing, the letter "N" is defined as maximum number of beams. "N" can also be considered as the total number of beams in the beam pool. Completing the variables is the letter "P", which defines the number of beams constrained in a group that may be allocated to each phased array antenna aperture.

[0054] Column 216 of table 214 presents the number of components used by an antenna system using dedicated beamformers. In particular, a total of L multiplied by M antenna elements (represented as LM) arc distributed among the phased array antenna apertures and are each connected to one N/P-way power divider. A total of LMN/P P-way power dividers are also included in the dedicated beamformers along with LMN phase
shifter/attenuators. To produce the beams, LN M-way combiners are included in the dedicated beamformers.

[0055] Column 218 of table 214 presents the number of components used by an antenna system that includes a selector network for sharing beamformers such as beamformers 168, 170, 172, and 174 shown in FIG 5 and FIG 6. The number of total antenna elements (LM) and N/P-way power dividers (LM) used by the antenna system that shares beamformers is equivalent to the number used by the antenna system with dedicated beamformers. However, a number of selectors (e.g., switches) are included in the selector network used to share beamformers. In particular, MN/P L-way selectors are included in antenna system that shares beamformers. By allowing beamformers to be shared, less P-way power dividers, phase shifter/attenuators, and M-way combiners are used by the shared beamformers. In particular, MN/P P-way power dividers, MN phase shifter / attenuators, and N M-way combiners are used to produce and allocate the N beams in an antenna system that shares beamformers.

[0056] By including selectors to share beamformers, less components are needed in comparison to an antenna system that uses dedicated beamformers. These component savings are presented in column 220 of table 214. For example, by implementing beamformer sharing, the number of P-way power dividers, phase shifter/attenuators, and M-way combiners are reduced. As shown in column 220, the number of P-way power dividers is reduced by (L-1)MN/P, the number of phase shifter/attenuators is reduced by (L-1)MN, and the number of M-way combiners is reduced by (L-1)N. By reducing the components in the shared beamformers, payload space and mass is conserved along with reducing cost. Column 222 of Table 214 presents the number of components added by implementing a shared beamformer scheme as opposed to a dedicated beamformer scheme. In particular, MN/P selectors are added by sharing beamformers. However, these additional selectors are less in number than the components eliminated, as shown in
While the above-described system discloses selecting signals received at one or more phased array antenna elements, other operational configurations are possible. For example, signals may be selected for transmission over one or more phased array antenna elements. In such a configuration, the shared beamformers are designed for transmission. Combiners (e.g., 3-way signal combiner 168) are replaced with signal dividers that provide signals to the selector network(s) for directing the signals to allocated phased array antenna elements. Additionally, the low noise amplifiers (e.g., low noise amplifier 48) are replaced with power amplifiers to drive the phased array antenna elements. Additionally components may be also be added to provide signal transmission. Furthermore, in some configurations, shared beamformers may provide both signal transmission and reception capabilities.

In other operational configurations, both shared and dedicated beamformers may be implemented into a phased array antenna system. Beamformer sharing may also depend upon a signal parameter. In one configuration, beams may be shared based on signal frequency or polarization. For example, eight beams may be shared among apertures that transmit or receive Ka-band signals while only four beams are shared among apertures that transmit or receive Ku-band signals. Various types of antenna elements may be implemented in the antenna systems that included a selector network to share beams. Also, multi-beam phased arrays, multi-beam reflector arrays, or other types of antenna elements or apertures that are well known to one skilled in the art or antenna and antenna system design may be implemented. By implementing a shared beamformer, beams may be shared among different size arrays. For example, beams may be shared between one aperture that includes a large number of antenna elements and another aperture that includes relatively fewer antenna elements. In still another implementation, a shared beamformer may be implemented to share beams among antenna elements or groups of
antenna elements that are all included in the same phased array antenna aperture.

[0059] Besides using a selector network to share one or more beamformers among phased array antenna elements, a selector network (or networks) may be implemented to share beamformers among other signal processing modules. For example, a selector network may be used to select a group of beams (from a plurality of beam groups) for further processing. Once selected, the beam group may, for example, be further beamformed to focus on a particular region that is covered by the group of beams.

[0060] Referring to FIG 8, an illustrative map 224 of the United States represents coverage provided, for example, by a phased array antenna system of a satellite. In this example, two regions of the country are covered by respective groups of beams. Referring to the West Coast, three relatively broad beams 226, 228, and 230 are produced by the satellite phased array system. In this example aperture 14 produces beams 226-230, which combined produce a beam cluster that provides partial coverage for a field of view 232 associated with the aperture. Similarly, aperture 16 of the phased array system provides coverage to the northeast portion of the United States. In particular, three broad beams 234, 236, and 238 produce a beam cluster that provides partial coverage for a field of view 240 associated with aperture 16.

[0061] As described above, by implementing one or more selector networks, a beamformer may be shared by the phased array system of the satellite. By sharing the beamformer, the beams produced by the phased array system may be allocated, e.g., for East Coast and West Coast coverage. For example, three or more beams may be allocated for West Coast coverage to produce beam cluster 232 and three or more may be allocated for East Coast coverage to produce beam cluster 240.

[0062] In addition to incorporating one beamformer stage to produce a cluster of beams, a second beamformer stage may be incorporated to beamform one or more of the
beams included in one or more of the beam clusters. This additional beamforming allows a beam with a relatively narrow beamwidth to be produced from one or more of the beams included in a cluster (which typically have broader beamwidths). As an illustration, beam 226 is beamformed to produce narrow beams 242, 244, 246. These narrow beams 242-246 may be steered to focus on a region in which communication traffic is particularly heavy. However, the steering of each narrow beam is constrained to the coverage area provided by beam 226. Similarly, additional beamforming may also be performed on the beams 228 and 230. For this particular illustration, beam 228 is beamformed to produce narrow beams 248 and 250 while beam 230 is beamformed to produce narrow beams 252, 254, and 256. Similarly, to illustrate a second level of beamforming for the beams produced by aperture 16, beam 236 and 238 are beamformed to respectively produce narrow beams 258, 260, 262 and 264. Each of these narrow beams 242-264 may be steered for covering any location within the respective broader beam that is used to produce the narrow beam. For example, narrow beam 260 may be steered to any location that is covered by beam 238. Similarly, beam 258 may be steered to any location that is covered by beam 236.

[0063] Similar to sharing a beamformer to allocate beams to a particular portion of a phased-array antenna system (e.g., an aperture), a second beamforming stage may be shared such that some or all of the beams in a beam cluster may be selectively beamformed to produce one or more beams with relatively narrow beamwidths such as beams 242-264.

[0064] In this particular arrangement, each beam cluster includes three broad beams (e.g., beams 226, 228, 230 and beams 234, 236, 238). However, more or less beams may be included in either or both clusters. Furthermore, if a suitable selector network is provided, the narrow beams formed by the second beamforming stage may be flexibly allocated between the broad beams (e.g., 226, 228, 230, 234, 236, 238). For example, six beams may be allocated to beam cluster 232 and only two beams may be allocated to beam cluster 240. By connecting one or more of the beams included in either cluster of beams,
one or more narrow beams may be produced (by a beamforming stage) and steered to any
direction within the coverage area of the broader beam from which the narrow beam is
produced.

[0065] Similar to the apertures mentioned above, phased array apertures with various
c characteristics may be implemented to produce the cluster of beams in field of view 232
and/or 240. For example, apertures that operate with various frequencies and polarizations
may be implemented. Some apertures may operate with different frequencies and/or
polarizations and may be pointed to the same or different geographic areas (e.g., Vertical
polarization and horizontal polarization for a GEO satellite). Alternatively, apertures may
operate with a similar frequency and/or polarization and be pointed the same or different
geographic areas (e.g., east and west of a LEO spacecraft).

[0066] Referring to FIG 9, an illustrative design is shown for using a plurality of
beamforming stages. In this embodiment, a first beamforming stage may take the form of
one or more cluster formers 268 and 270 and a second beamformer stage 272 may take the
form of beamformer 116 above, as examples. To share this second beamforming stage, a
selector network 266 is used in a similar manner to share a beamformer for beam allocation
(as described above). To illustrate some of the operations of selector network 266,
respective elements 36-46 included in apertures 14 and 16 are connected to cluster-formers
268 and 270. In particular, the elements are connected to the cluster-formers via low noise
amplifiers 48-58. In general, cluster-formers 268 and 270 combine signals from the
respectantenna elements to produce one or more relatively broad beams. For example,
with reference to FIG 8, beam-cluster 268 may use signals received by aperture 14 to
produce beams 226-230. Similarly, signals received by aperture 16 may be preferably
provided to cluster-former 270 to produce beams 234-238.

[0067] As mentioned, a second beamformer 272 may be used to produce one or more
narrow beams from the beam clusters. For example, beams produced by cluster-former
268 (e.g., beams 226-230) may be beamformed to produce one or more narrow beams (e.g., beam 242-256) that may be steered to any region within the coverage area of the respective beam from which they are produced. Similarly beams produced by cluster-former 270 (e.g., beams 234-238) may also be beamformed by beamformer 272 to produce one or more narrow beams (e.g., beam 258-264) that may be steered within the coverage area of the respective beam(s) from which they are produced.

[0068] By incorporating selector network 266 between cluster-formers 268 and 270 and the second beamforming stage 272, signals from an appropriate cluster-former are provided to the second beamformer. For example, East Coast communication traffic may be heavier in the morning (than West Coast communication traffic) due to time zone differences. Thus, to provide an appropriate number of narrow beams to the East Coast, signals from cluster-former 270 may be provided to second beamforming stage 272. To provide these signals, selector network 266 may be remotely controlled (e.g., via an RF link) to provide the signals from cluster-former 270 to beamformer 272. Correspondingly, late afternoon communication traffic on the West Coast may be significantly heavier than communication traffic on the East Coast. During this time period, a need may arise to produce one or more narrow beams for West Coast coverage that are within the coverage region of beam cluster 232. To produce the narrow beam (or beams), selector network 266 may preferably provide signals from cluster-former 268 to second beamforming stage 272. In this exemplary design, beamformer 272 includes N outputs (designated as beam 1, beam 2, ..., beam N) that may be used to provide narrow beams to other components and/or equipment (e.g., a receiver, etc.) included in the satellite (or other similar platform). Also, while this illustrative design includes two cluster-formers 268, 270, one selector network 266, and one second beamforming stage 272, in other designs, the number of select networks, cluster-formers, and beamformers may be scaled to accept signals from more or less elements and/or phased array apertures.
By implementing selector network 266, second beamforming stage 272 is shared among cluster-former 268 and cluster-former 270. By sharing beamformer stage 272, the number of hardware components is reduced, which correspondingly reduces the cost and weight of a payload module such as payload module 32. Furthermore, by sharing beamformer stage 272, the beams from cluster-formers 268, 270 may be selected depending upon signal traffic volume or another parameter (e.g., frequency, polarization, etc.). In this exemplary design, selector network 266 was positioned between the set of cluster-formers 268, 270 and the second beamforming stage 272. However, in other designs, one or more selector networks may be arranged in a different manner. Furthermore, the architecture and mode of operation of selector network 266 may be similar to selector network 118 (e.g., selector 118A or 118B shown in FIGS. 5 and 6, respectively). Selector network 266 permits beams to be assigned individually (as shown in FIG 5) or in groups (as shown in FIG 6) to any beam cluster. Selector network 266 may also select between beam clusters created by one or more apertures. Typically, switching operations of selector network 266 are performed in a manner such that the signals combined by beamformer stage 272 are from beam clusters produced by the same aperture and are steered in the same direction.

Referring to FIG 10, a block diagram is shown that represents a portion of an exemplary cluster-former 274. This design may be implemented, for example, in cluster-formers 268 and 270 (shown in FIG 9). As mentioned above, cluster-former 274 provides a first beamforming stage that uses signals received from an aperture (such as aperture 14) to produce one or more relatively broad beams. In this implementation, to produce the broad beams, signals received from elements 36, 38, and 40 are provided to respective power dividers 280, 282, and 284. In this illustration, three power dividers are incorporated into cluster former 274, however, in other arrangements additional power dividers may be incorporated. Each of the power dividers split their respective input signals dependent upon the number of beams to be formed. For cluster-former 274, each
The power divider performs a three-way split of their respective input signals for forming three broad beams. However, this splitting is scalable for producing more or less board beams. The split signals from each power divider are respectively provided to phase-shiflers/attenuators 286, 288, 290, 292, 294, 296, 298, 300 and 302 that may individually attenuate (represented by $\alpha$) and/or adjust the phase (represented by $\phi$) of the input signal. In general, attenuation and phase adjustments are performed to produce and steer the one or more broad beams. To form the individual beams, adjusted output signals of the phase-shiflers/attenuators are provided to respective power combiners 300, 302, and 304. To produce each beam, a signal received by each element 36-40 is provided to each power combiner. For example, phase-shifter/attenuator 286 provides a signal that is received from element 36 while phase-shiflers/attenuators 292 and 298 respectively provide signals from elements 38 and 40. These three signals are combined in power combiner 300. Each of the power combiners combine the attenuated and/or phase shifted input signals to produce a broad beam. Again, while three power combiners are implemented in this cluster-former to produce three distinct beams, in other arrangements, the number of power combiners may be increased or decreased to produce more or less broad beams.

[0071] Referring to FIG 11, various designs may be implemented to select signals for initial beamforming and subsequent beamforming. In this particular design, signals are received from respective element groups in apertures 14 and 16 in a similar manner as described in regards to the apertures shown FIG. 9. Cluster-formers 306 and 308 respectively receive and beamform the signals to produce one or more beam clusters. Signals representing the beams produced by the cluster-formers are provided to respective selector networks 310 and 312 that select signals to additional beamforming. Second beamforming stages 314 and 316 produce one or more narrow beams that are passed to another selection network 318 that provides another round of selection. These narrow beams may be steered to any angular direction within coverage area provided by the beam used to produce the narrow beam(s). By selecting one or more of these narrow beams,
selector network 318 may provide these selected beams to other equipment and/or components for additionally processing. In this example, one or more narrow beams are provided to another beamforming stage 320 that produces one or more beams with even narrower beamwidths. The beams that are output from beamforming stage 320 may be steered. However, these beams are also constrained to the coverage area of the narrow beams used to produce the narrower beams.

[0072] Similar to using a selector network to share a beamformer for allocating a pool of beams, a selector network may be used to share a beamformer for allocating a pool of beams among clusters of beams. Thereby, if one cluster provides better coverage (e.g., for a high traffic situation), more beams may be allocated to that cluster. Later, when another cluster is providing more useful coverage, the selector network may re-allocate the beams to this other cluster. Furthermore, by sharing a beamformer among two or more cluster-formers, the number of hardware components is reduced, which correspondingly reduces the cost and weight of the payload module. Furthermore, by sharing a beamformer among beam clusters, the pool of beams produced by the beamformer may be flexibly allocated among the clusters depending upon issues such as orientation the satellite (or other type of platform), signal traffic volume, or beam parameter (e.g., frequency, polarization, etc.), etc.

[0073] Also similar to sharing a beamformer to allocate beams among phased array antenna apertures, the number of beams allocated to a beam cluster may be constrained to a particular group size. For example, a beam cluster may be constrained such that the narrow beams produced from the beam cluster are allocated in groups of two. So, using this constraint, e.g., zero, two, or four beams may be allocated to the beam cluster. As mentioned above, to constrain the number of beams allocated, signal dividers (e.g., power dividers) may be included in one or more of the implemented selector networks. For example, a signal divider may be respectively inserted between each selector and each
phase shifter/attenuator.

[0074] Alternatively, beams may be individually allocated or may not be constrained to one group size. Furthermore, multiple group sizes may be implemented with similar or dissimilar sizes. Along with constraining beam groups to a particular number, grouping may also be constrained by one or more other parameters. For example, beams may be grouped by frequency band (e.g., C-band, Ku-band, etc.), polarization (e.g., linear vertical, linear horizontal, right hand circular, left hand circular, elliptical, etc.), or one or more other parameters.

[0075] A number of implementations have been described. Nevertheless, it will be understood that various modifications may be made. Accordingly, other implementations are within the scope of the following claims. For example, any of the embodiments discussed above, or of the present invention generally, maybe applied in the transmit mode, additionally or alternatively to the receive mode, as will be appreciated by those skilled in the art.
WHAT IS CLAIMED IS:

1. A phased array antenna system, comprising:
   a first beamformer configured to produce at least a first antenna beam from
   at least two electromagnetic signals that are respectively received by at least two
   phased array antenna elements; and
   a selector configured to provide the first antenna beam to a second
   beamformer that is configured to produce at least a second antenna beam, wherein
   coverage provided by the second antenna beam is at least partially constrained by
   the coverage provided by the first antenna beam.

2. The phased array antenna system of claim 1, wherein the pointing direction of the
   second antenna beam is partially constrained by the beamwidth of the first antenna beam.

3. The phased array antenna system of claim 1, wherein the first antenna beam has a
   larger beamwidth than the second antenna beam.

4. The phased array antenna system of claim 1, wherein the phased array antenna
   elements are included in the same phased array aperture.

5. The phased array antenna system of claim 1, wherein the phased array antenna
   elements are included in different phased array apertures.

6. The phased array antenna system of claim 1, wherein the first beamformer includes a
   phase shifter configured to adjust the phase a signal associated with at least one of the
   received signals.
7. The phased array antenna system of claim 1, wherein the first beamformer includes an attenuator configured to attenuate a signal associated with at least one of the received signals.

8. The phased array antenna system of claim 1, wherein the selector includes a switch.

9. The phased array antenna system of claim 1, wherein the selector includes a two-way switch.

10. The phased array antenna system of claim 1, wherein the selector includes a semiconductor switch.

11. The phased array antenna system of claim 1, wherein the selector includes a mechanical switch.

12. The phased array antenna system of claim 1, wherein the selector includes a ferrite switch.

13. The phased array antenna system of claim 1, wherein the selector includes an optical switch.

14. The phased array antenna system of claim 1, wherein the selector includes a digital switch.

15. The phased array antenna system of claim 1, wherein the selector executes instructions to provide first antenna beam to the second beamformer.
16. The phased array antenna system of claim 1, wherein the first beamformer, the selector, and the second beamformer are included in an integrated package.

17. A phased array antenna system comprising a plurality of sets of antenna elements configured to transmit, receive, or both, a set of signals, the phased array antenna system comprising:

   a first set of antenna elements associated with a first aperture and coupled to a first beamforming stage configured to produce at least one first antenna beam;

   a second set of antenna elements associated with a second aperture and coupled to a second beamforming stage configured to produce at least one second antenna beam;

   a selector coupled to the first beamforming stage and the second beamforming stage and configured to allocate antenna beams from the at least one first antenna beam and the at least one second antenna beam to a third beamforming stage; and

   the third beamforming stage configured to generate at least one third antenna beam, wherein coverage provided by the at least one third antenna beam is at least partially constrained by the coverage provided by the at least one first antenna beam, or by the at least one second antenna beam or both.

18. The phased array antenna system of claim 17, wherein the pointing direction of the at least one third antenna beam is partially constrained by the beamwidth of the at least one first antenna beam, or the at least one second antenna beam or both.

19. The phased array antenna system of claim 17, wherein at least one of the at least one first antenna beam and at least one second antenna beam has a larger beamwidth than the at least one third antenna beam.
20. The phased array antenna system of claim 17, wherein the phased array antenna elements are included in the same phased array aperture.

21. The phased array antenna system of claim 17, wherein the phased array antenna elements are included in different phased array apertures.

22. The phased array system of claim 17, wherein the selector includes at least one switch.

23. A method of producing electromagnetic beams, comprising:
   receiving electromagnetic signals from a first and second phased array antenna element;
   beamforming the electromagnetic signals to produce at least a first antenna beam; and
   selecting to beamform the first antenna beam to produce at least a second antenna beam, wherein coverage provided by the second antenna beam is at least partially constrained by the coverage provided by the first antenna beam.

24. The method of claim 23, further including:
   beamforming at least the first antenna beam to produce the second antenna beam.

25. A method of producing electromagnetic beams, comprising:
   receiving electromagnetic signals from a first and second phased array antenna element;
   beamforming the electromagnetic signals to produce at least a first antenna beam;
beamforming at least the first antenna beam to produce at least a second antenna beam, wherein coverage provided by the second antenna beam is at least partially constrained by the coverage provided by the first antenna beam; and selecting the first antenna beam from other produced beams.

26. The method of claim 25, further comprising:

   constraining the selecting of produced beams to a particular number of beams.

27. A method of receiving, transmitting, or both, electromagnetic beams in a phased array antenna comprising a plurality of sets of antenna elements configured to transmit, receive, or both, a set of signals, the method comprising:

   generating at least one first antenna beam from a first beamforming stage configured for coupling to a first set of antenna elements and a second set of antenna elements;

   allocating by a selector the at least one first antenna beam to inputs of a second beamforming stage; and

   generating at least one second antenna beam from the second beamforming stage, wherein coverage provided by the at least one second antenna beam is at least partially constrained by the coverage provided by the at least one first antenna beam.

28. A phased array antenna system comprising a plurality of sets of antenna elements configured to transmit, receive, or both, a set of signals, the phased array antenna system comprising:

   a first set of antenna elements associated with a first aperture and coupled to a first beamformer configured to produce at least one first antenna beam;
a first selector coupled to the first beamformer and coupled to a second beamformer, the second beamformer configured to produce at least one second antenna beam that is partially constrained by the at least one first antenna beam;

a second set of antenna elements associated with a second aperture and coupled to a third beamformer configured to produce at least one third antenna beam;

a second selector coupled to the third beamformer and coupled to a fourth beamformer, the fourth beamformer configured to produce at least one fourth antenna beam that is partially constrained by the at least one third antenna beam;

a final selector coupled to the second beamformer and the fourth beamformer and configured to allocate antenna beams from the at least one second antenna beam and the at least one fourth antenna beam; and

a final beamforming stage coupled to the final selector and configured to generate at least one final antenna beam, wherein coverage provided by the at least one final antenna beam is at least partially constrained by the coverage provided by the at least one second antenna beam, or by the at least one fourth antenna beam or both.

29. A phased array antenna comprising a plurality of sets of antenna elements configured to transmit, receive, or both, a set of signals, the phased array antenna comprising:

    a plurality of beamformers and at least one selector configured to couple to a first set of radiating elements and a second set of radiating elements to generate at least one first antenna beam and to generate there from at least one second antenna beam, wherein coverage provided by the at least one second antenna beam is at least partially constrained by the coverage provided by the at least one first antenna beam.

Table 214

L = Number of phased array antenna apertures
M = Maximum number of beams per phased array antenna aperture
N = Number of beams per phased array antenna aperture
P = Number of beams per phased array antenna aperture
