ABSTRACT

A system for process control comprises a server digital data processor and a client digital data processor that are coupled by a network, such as the Internet or an Intranet. The server digital data processor, which is additionally coupled to a control/sensing device and any associated interface equipment (collectively, referred to as "process control apparatus"), includes a command processor that transfers information between the network and the process control apparatus. The client digital data processor includes an information client (e.g., a so-called Internet web browser) capable of requesting and receiving an applet from the server digital data processor. The information client, further, defines a hardware-independent and operating system-independent virtual machine environment within the client digital data processor. The client digital data processor executes, within that virtual machine environment, an applet for configuring the client digital data processor as a "process controller" that establishes communications over the network with the command processor and that monitors and/or controls the process control apparatus via those communications.
CONTROL SYSTEM METHODS AND APPARATUS WITH SERVICES

BACKGROUND OF THE INVENTION

[0001] The invention pertains to process control and has application to remote process control.

[0002] Process control refers to the control of the operational parameters of a system by monitoring one or more of its characteristics over time. It is used to ensure that the quality and efficiency of the system remain within desired parameters over the course of time. While process control is typically employed in the manufacturing sector for process, repetitive and discrete manufactures, it also has wide application in service industries, such as environmental control.

[0003] Process control equipment typically utilizes control/sensing devices that are physically integrated into the systems being controlled. For example, a thermostat is typically used in environmental control to ensure that building temperatures remain within specified parameters. Likewise, flow control sensors and automated valves are typically used in process manufacturing to insure proper fluid flow volumes.

[0004] Though in early process control systems, control/sensing devices were typically stand-alone units, modern process control systems provide central workstations for monitoring and controlling the control/sensing devices. Particularly robust systems are the I/A Series™ industrial automation systems designed, manufactured and marketed by the assignee hereof, The Foxboro Company, of Foxboro, Mass., USA. In these systems, multiple control/sensing devices are coupled by way of buses to control stations which, in turn, are coupled by way of a local area network (LAN) to one or more operator workstations.

[0005] The I/A Series systems are built around the client/server model. Client applications software executing on the workstations exchange information with the control/sensing devices via a server, referred to as the “object manager,” executing in distributed fashion in the control stations. Upon request by a client application, the server creates, locates, accesses and updates data structures (“objects”) storing information on the status of at least selected control/sensing devices. For example, a client application that displays temperatures sensed by a thermocouple requests that the server create an object storing a temperature reading from the thermocouple and that the server notify the client each time the temperature changes.

[0006] Although modern process control systems, such as the I/A Series systems, have proven quite successful, to date they have provided only limited remote access capabilities. Thus, while numerous operator workstations may reside within the factory or facility in which the control/sensing devices are disposed, it has traditionally proven difficult to access and control those devices outside those areas.

[0007] Remote access and control of processes is desirable for a number of purposes. A plant manager who is “on the road,” for example, may wish to monitor the plant processes whilst travelling. By way of further example, the manufacturer of process control equipment may require remote access to a plant’s control/sensing devices in order to provide technical support.

[0008] An object of this invention is to provide improved methods and apparatus for process control.

[0009] Another object of the invention is to provide such methods and apparatus as permit monitoring and control of remote processes.

[0100] Still another object of the invention is to provide such methods and apparatus as can be readily adapted to existing automated process control systems.

[0110] Yet still another object of the invention is to provide such methods and apparatus as can be implemented without undue expense and without undue consumption of resources.

SUMMARY OF THE INVENTION

[0112] The aforementioned objects are among those attained by the invention, which provides, in one aspect, a system for process control comprising a server digital data processor and a client digital data processor that are coupled by a network, such as the Internet or an Intranet. The server digital data processor, which is additionally coupled to a control/sensing device and associated interface equipment (collectively, referred to as “process control apparatus”), includes a command processor that transfers information between the network and the process control apparatus.

[0113] The client digital data processor includes an information client (e.g., an Internet web browser) capable of requesting and receiving an applet from the server digital data processor. That information client, further, defines a hardware-independent and operating system-independent virtual machine environment within the client digital data processor.

[0114] The client digital data processor executes, within that virtual machine environment, an applet that configures the client digital data processor as a “process controller” that establishes communications over the network with the command processor and that monitors and/or controls the process control apparatus via those communications. The applet is intermediate or executable code that is suitable for interpretation or execution within the virtual machine environment and that is hardware-independent, operating system-independent and windows system-independent.

[0115] In further related aspects, the aforementioned applet can be, for example, JAVA programming language bytecode, and the virtual machine environment can be that created by a JAVA-enabled web browser.

[0116] According to other aspects of the invention, the command processor in a system for process control as defined above provides services (i.e., “software services”) for access and modification of information regarding the process control apparatus. These services can permit, for example, the creation of a data structure object that stores information about the process control apparatus and that associates a name with that object; the destruction of such an object; the accessing of information in such an object; the updating of information in such an object; the determination, from an object name, of the physical address of the object; and the notification of changes in information stored by the object. The process controller generates and transmits over the network to the command processor requests for such services in order to monitor and/or control the process control apparatus.

[0117] A further aspect of the invention provides a system as described above in which the process controller generates and transfers commands (e.g., requests for service) over the network to the command processor in order to effect a transfer from the command processor of information regarding a status of the process control apparatus. The command processor responds to those requests by generating information on the status of the process control apparatus and transferring it back to the process controller over the network. The process controller can, for example, generate a user display based on that information.
In a related aspect, the command processor responds to selected commands (i.e., requests for event-driving access) by notifying the process controller of changes in the status of at least selected aspects of the process control apparatus. By way of example, where the process control apparatus includes a thermocouple, this aspect of the invention permits notification of the command processor whenever the thermocouple senses a change in temperature that exceeds a predetermined delta value.

Still further aspects of the invention provide process control systems as described above in which the server digital data processor includes an information server (e.g., a hyper-text transfer protocol server). An information client (e.g., web browser) in the client digital data processor establishes communications with the information server over the network and receives therefrom a hypertext markup language (HTML) document referencing the applet. The web browser generates a user display of that document and, in response to a user command, transfers to the information server a request for the applet.

Yet still further aspects of the invention provide systems for process control in which a first digital data processor executes a JAVA applet within a virtual machine environment defined on the digital data processor. The applet configures the digital data processor to generate a message to invoke a method in connection with monitoring and/or controlling a process control apparatus. An object manger, which is in communication with the JAVA applet, responds to the message for invoking the method.

Other aspects of the invention provide methods for process control paralleling the operations of the systems described above.

These and other aspects of the invention are evident in the drawings and in the detailed description that follows.

BRIEF DESCRIPTION OF THE DRAWINGS

A further understanding of the invention may be attained by reference to the drawings, in which

FIG. 1 depicts a system for process control according to the invention; and

FIG. 2 is an event trace diagram depicting messages that flow among the components of the system of FIG. 1 in an embodiment for graphing trends in process control apparatus data values.

DETAILED DESCRIPTION OF THE ILLUSTRATED EMBODIMENT

FIG. 1 depicts a system 10 for process control according to the invention. The system includes client digital data processors 12, 14 and server digital data processor 16. The digital data processors 12, 14, 16 are connected to one another via network 18.

Server digital data processor 16 is, additionally, coupled to process control apparatus 19a-19e via bus/network structure 20 and control stations 23a-23e, as shown. The process control apparatus includes conventional control/sensing devices, which are shown in the illustration as flow control valves, and associated interface equipment, which are marked “FBM” in the illustration. The process control apparatus 19a-19e are intended to represent any conventional control/sensing devices and interface equipment of the type conventionally used to monitor and control processes—including, by way of non-limiting example, continuous, repetitive and discrete processes, and environmental control processes, among others.

As discussed below, control stations 23a-23e include objects storing information that control, and reflect the status of, their associated process control apparatus 19a-19e. The control stations 23a-23e also execute object management software (marked “OM”) that manages and oversee access to those objects. The control stations 23a-23e are of the type conventionally used in a distributed process control architecture. Preferred such control stations are commercially available from the assignee hereof, The Foxboro Company, as part of its I/A Series industrial automation systems.

The digital data processors 12, 14, 16 comprise conventional digital data processing systems of the type commercially available in the marketplace. Though client digital data processors 12, 14 are illustrated as a portable computer and a personal digital assistant, respectively, those skilled in the art will appreciate that these may comprise other computing systems, such as desktop computers and workstations, as well. The digital data processors 12, 14, 16 may be coupled to the network 18 directly, as shown, or other networks (e.g., LANs and WANs), routers, or interface servers (not shown).

The network 18 comprises any conventional digital data processing network (e.g., LAN or WAN), cable television-based network, wireless network and/or any telecommunications-based network capable of supporting communications between server digital data processor 16 and client digital data processors 12, 14. The network 18 preferably comprises the global Internet and/or an enterprise-based Intranet supporting communications via the TCP/IP protocol (i.e., the current standard protocol of the Internet). Utilization of networks supporting this protocol is advantageous insofar as it permits the use of commercially available products (such as web browsers, discussed below) in components of the illustrated embodiment. Those skilled in the art will appreciate that the invention is applicable to networks supporting other protocols, as well.

The digital data processors 12, 14, 16 execute software that respectively configure them for communication over the network 18. For example, they execute protocol stacks and other software that permit them to establish and carry out communications utilizing the TCP/IP network protocol. In addition, they execute information client/server software that configures them to carry on high-level communications, particularly, over the Internet.

More particularly, in the illustrated embodiment, server digital data processor 16 includes information server 20 responsible for establishing communications over network 18 with information clients executing on the client digital data processors 12, 14.

The information server 20 is preferably a hyper-text transfer protocol (HTTP) server capable of transferring markup language information and, particularly, hypertext markup language (HTML) documents, to the client digital data processors 12, 14. In alternative embodiments of the invention, information server 20 can comprise any other such server capable of supplying an applet to the client digital data processors 12, 14 in response to requests by them.

The information server 20 establishes communications with the client digital data processors 12, 14 and, particularly, their respective information clients in the conventional manner known in the art. Once communications are established, the information server transfers the informa-
tion client an applet that executes within the virtual machine environment and that monitors and/or controls the process control apparatus via communications with a command processor in the server digital data processor 16, as discussed below.

[0035] The client digital data processors 12, 14 include information clients 22, 24, respectively, that are responsible for initiating and conducting at least preliminary communications with the server digital data processor 16 over the network 18. The information clients 22, 24, particularly, (1) initiate communications with the information server 20 over the network, (2) request and receive from the information server 20 an applet, and (3) define a platform-independent (i.e., a hardware-independent, operating system-independent and window system-independent) virtual machine environment within the respective client digital data processor 12, 14. Such information clients are, in one embodiment, JAVA-compliant web browsers including the HotJava browser from Sun Microsystems, Inc., NetScape Navigator from Netscape Communications Corporation, and the Internet Explorer from Microsoft Corporation.

[0036] As used herein, an applet is intermediate or executable code suitable for interpretation or execution within the virtual machine environment and that is hardware-independent, operating system-independent and windows system-independent. Preferred applets are in the form of Java bytecode of the type generated by the Java language compiler available from Sun Microsystems, Inc.

[0037] The aforementioned preferred web browsers define a preferred virtual machine environment comprising the Java programming language run-time platform and Java interpreter.

[0038] Although a preferred information client is a web browser, the invention can be practiced with other information clients capable of (1) initiating communications with the information server 20, (2) requesting and receiving from the information server 20 an applet, and (3) defining a platform-independent (i.e., a hardware-independent, operating system-independent and windows system-independent) virtual machine environment within the respective client digital data processor 12, 14 for execution of such an applet.

[0039] In addition to information server 20, server digital data processor 16 includes command processor 25, comprising front end 25a, interface section 25b, and an object manager 25c. Together, these transfer information between the network 18 and process control apparatus 19a-19e. As shown in the illustration, the object manager functionality is distributed among the control stations 23a-23e. Each object manager maintains the data structures—to wit, objects—that control and reflect the status of its associated process control apparatus 19a-19e.

[0040] The object manager 25c provides software services for access that permit the creation of named objects; destruction of such objects; accessing and updating of information in the objects; the locating of objects within the distributed process control architecture; and notification of changes in the information stored in objects (i.e., event-driven notification).

[0041] As noted, the object manager 25c allows uniquely named objects to be distributed over the control stations 23a-23e in a location-independent way. Using the object manager 25c (via front end 25a), applets 26, 28 may create, read, write, and destroy instances of objects, which are subtyped into four categories: variable—used to contain an instance of any scalar data type (e.g., int, float, etc.) or a string; alias—used to contain a string which refers to the name of another object; device—used to identify a station or device in the system. An instance of a device type object contains no explicit state—the name of the object is itself the state; and process—used to identify an executing process in the system. A process object is identical to a device object in that there is no explicit state.

[0042] As indicated above, in order to manipulate instances of objects, the object manager 25c provides life cycle services, access services and connection services. Life cycle services are used to create, name, and destroy shared objects; to register the name of process-control objects; and to find the location of any object. Access Services are used to get and set the value of one or more process-control and/or shared objects. Typically, access services are suitable for situations where a single transfer of data is sufficient.

[0043] Connection services are also used to get and set the value of one or more process-control and/or shared objects. However, these services are more suited for situations where multiple transfers of data are expected. In addition, connection services provide the ability for a client to be continuously updated with the value of an object when it exceeds a specified delta.

[0044] The object manager 25c relies upon the use of broadcasts over bus structure 30 in order to perform the above services. For example, when an applet 26, 28 makes an access request on an object by name, the object manager 25c will broadcast the access request to all stations 23a-23e, if the object manager 25c does not know the location of object. Each station 23a-23e then determines if it is the one that hosts the requested object. Only the station that hosts the named object responds to the request.

[0045] A preferred object manager 25c is that commercially available from the assignee hereof, The Foxboro Company, as part of its I/A Series of industrial automation systems. A software interface, or "API," of that preferred object manager is described in publically available documentation, including the document entitled "Object Manager Calls," a copy of which is filed as an appendix herewith.

[0046] The command processor front end 25a executes on server digital data processor 16, configuring it to respond to requests from applets 26, 28 to establish communications with them over the network 18. Once communications are established, the front end 25a responds to requests received from applets 26, 28 over network 18 to transfer information to and from process control apparatus 19a-19e via the object manager 25c.

[0047] Particularly, the front end 25a responds to requests received over the network in TCP/IP protocol to generate calls to object manager 25c in accord with its aforementioned API. Moreover, the front end 25a responds to information generated by the object manager 25c in response to those calls by transmitting that information back over the network 18, in accord with the TCP/IP protocol to the applets 26, 28. In a preferred embodiment, the front end 25a presents a simplified interface to the object manager 25c, e.g., permitting applets 26, 28 to make requests and receive responses in the form of text strings, as discussed below.

[0048] Software implementing a preferred front end 25a as a Java programming language application is filed as appendix hereto. Those skilled in the art will appreciate that alternate embodiments may implement the front end in other program-
ming languages suitable for, or that can be adapted to, provide an interface between the network 18 protocol and the object manager 25c.

[0049] Interface section 25b provides a software interface between the front end 25a and the object manager 25c. As noted above, in a preferred embodiment, the front end 25a is implemented as a Java programming language application. The object manager 25c, on the other hand, is implemented as a C programming language application and, accordingly, its API includes pointer-based parameters. The interface section 25b compensates for the inability of the Java front end 25a to utilize pointer-based parameters, e.g., by converting them to arrays as discussed further below.

[0050] Software implementing a preferred interface section 25b in the C programming language is filed as appendix hereto. Those skilled in the art will appreciate that interface section 25b is optional and may be excluded in embodiments where the front end 25a can make calls directly to the object manager 25c.

[0051] The client digital data processors 12, 14 execute applets 26, 28 within the virtual machine environments defined by the information clients 22, 24. Each applet 26, 28 configures its respective client digital data processors as a process controller that establishes communications over the network 18 with the command processor front end 25a and that monitors and/or controls the process control apparatus 19a-19c via those communications. More particularly, the process controllers generate and transfer requests for service over the network 18 to the command processor 25 so as to effect the transfer of information controlling, and reflecting the status of, the process control apparatus 19a-19c. The process controllers also receive information from the command processor 25, e.g., for display to an operator.

[0052] As noted above, the applets 26, 28 comprise intermediate or executable code that is interpreted or executed with in the virtual machine environment defined by the information clients and that is hardware-independent, operating system-independent and windows system-independent. Source code for preferred applets, in the Sun Microsystems Java programming language, is provided in the appendix filed herewith.

[0053] A process control system constructed and operated in accord with system 10 of FIG. 1 can be employed in a wide variety of process control embodiments. One such embodiment is shown in FIG. 2 and described below. That embodiment provides for generation, by an applet executing on the client digital data processor, of graphs showing trends in data values of process control apparatus coupled to a server digital data processor.

[0054] FIG. 2 is an event trace diagram depicting messages that flow among the components of the system 10 of FIG. 1 in the above-mentioned embodiment. The components of the system 10 are shown in the event trace diagram as vertical lines with the name of the component at the bottom of the line. Messages are represented by arrows. Each message flows in the direction of the arrow from component to component. Messages that happen earlier in time are toward the top of the diagram.

[0055] Referring to FIG. 2, communication begins with the operator signaling the information client 22 to establish communications with the server digital data processor 16 over the network 18. The operator can signal the information client, e.g., a keyboard stroke or “mouse” click on the operator console (not shown). In the illustrated embodiment, the information client 22 is the Netscape web browser.

[0056] In response the operator’s request, the information client 22 generates and transmits over network 18 a request for connection with information server 20, e.g., an HTTP server, executing on server digital data processor 16. Once the connection is established, the HTTP server 20 sends to the web browser 22 an HTML page that references (i.e., provides an address for) a trend-graphing applet. The HTML page also optionally includes text and graphics describing the applet.

[0057] The web browser 22 displays the HTML on the operator console. If the operator signals the web browser 22 that he or she wishes to access the applet, the web browser 22 transmits to the HTTP server 20 over the network 18 a request for the applet. It will be appreciated that the applet may be transmitted to the web browser 22, along with an initial HTML document.

[0058] The HTTP server 20 responds to such a request for forwarding Java bytecode for the applet over the network 18 to the web browser 22. On receipt of the applet, the Java-compatible web browser 22 executes the applet 26 in the virtual machine environment defined in the web browser 22.

[0059] Once executing, the applet 26 sends a request to establish a separate communications link over the network 18 with the command processor front end 25a, e.g., a Java application executing on the server digital data processor 16. This separate connection is used by the applet 26 and the front end 25a to permit the exchange messages over the network and, particularly, to permit the applet 26 to make requests of the command processor 25 for process control apparatus data to be graphed.

[0060] Once communications are established, the applet 26, 28 generates a display on the operator console of the client digital data processor 12 and permits the operator to enter the names of process control apparatus data values (i.e., “points”) that are to be graphed. On the operator’s command, the applet 26 sends a request over the network 18 to the front end 25a specifying the OMP open service and listing the names of operator-specified points. The request is in text or ASCII format, e.g., “OMOPEN name1; name2; name3; etc.”

[0061] On receipt of the OMP open request, the front end 25a creates a data structure required by object manager 25c, to with an OM list, and includes in that data structure the names of the specified points. The front end 25a then makes an “omopen list” call to the object manager 25c utilizing the aforementioned API. A further understanding of the OM list data structure and of the “omopen list” call, as well as the other data structures and calls to the object manager 25c, may be attained by reference to the appendix filed herewith.

[0062] The object manager 25c responds to the omopen list call by querying the respective process control apparatus 19a-19c for current data values for the points. The object manager 25c returns those data values to the front end 25a which, in turn, generates and transmits to the applet 26, 28 a text message listing the initial data points. That message includes the keyword OM UPDATE, followed by the names and values of each of the points, e.g., “OM UPDATE point1=value; point2=value; etc.” The applet 26, 28 graphs those initial data points on the operator console.

[0063] The object manager 25c then begins looping, while awaiting further requests from the client applet 26 and while awaiting updates on the data values from the object manager 25c. When such an update is received, the front end 25a generates and transmits to the applet 26 a further text message
in the form “OMUPDATE point1=value; point2=value; etc.” listing the updated data values points. The applet 26 graphs those initial data points on the operator console at the end of the graph time interval.

[0064] The front end 25a continues looping and forwarding updates until the operator signals the applet 26 to stop trend graphing. In that event, the applet 26 sends a close request over the network to the front end 25a in the form of a text message “OMCLOSE.” On receipt of that request, the front end 25a, in turn, makes an omclose list call to the object manager 25c in accord with the aforementioned API. When that call returns, front end 25a sends an “OMCLOSEOK” text message to the applet, 26 causing it to clear the trend graph.

[0065] At this point, the operator can either specify new points to the applet 26 or can tell the web browser 22, 24 to connect to a different information server. If the operator signals that he or she wishes to connect to another server, the client applet 26 breaks the connection with the server by sending an “OMBREAK” message to the front end 25a over the network. The front end 25a then resets, and waits for the next connection.

[0066] In a preferred embodiment, the method illustrated in FIG. 2 is implemented in the Java programming language. As those skilled in the art will appreciate and as discussed above, all Java applets and Java applications run inside of a Java Virtual Machine. All implementations of the Java Virtual Machine are guaranteed to be identical regardless of the many hardware platforms on which they run.

[0067] The above-described trend-graphing client Java applet preferably runs in the Java Virtual Machine that is implemented by Netscape Navigator version 2.0. The trend client applet 26 is intended to be portable. So it only uses those classes that are present in all implementations of the Java systems. The trend-graphing applet 26 uses Java system classes to manage the screen, and connect to the trend server, and provide timing intervals.

[0068] The trend-graphing applet 26 implements classes that conduct all operator interaction. For example, it accepts the names of the points to be graphed. It also defines the GUI buttons used by the operator to signal when graphing is to start or stop. Further, the trend-graphing applet 26 plots X-Y axes, graph the points, and parses messages from the front end 25a.

[0069] The applet 26 also processes the following messages from the server: “OMUPDATE name2=value; name3=value; . . . ”; OMCLOSEOK.

[0070] The illustrated front end 25 (or “trend-graphing server”) is not portable to just any Java Virtual Machine because it must call outside of the Java environment to the object manager 25c. To do this, the trend server class is defined to have “native methods”. A “native method” is any member function of a class that is implemented in a language other than Java. A native method can enable access to functions and data that are “native” to a particular hardware platform operating system or a running application (like the object manager 25c). Native member functions are declared in the class as native. They are implemented in a library that is loaded by the Java environment at runtime. On Solaris this is a libfile.so file. On Windows NT this would be a library.dll file. The native methods, which constitute the interface 25b, are defined to create a new OM list, add a named point to the list, open the list, check the list for updates using dachange, and close the list. Source code for a preferred implementation of native methods is supplied in the appendix filed herewith.

[0072] The command processor front end 25a runs in a Solaris implementation of the Java Virtual Machine. The front end 25a processes the following messages from the applet 26: “OMOPEN name1; name2; name3; . . . ” (in response to which it creates a list with the specified points and opens the list); “OMCLOSE” (in response to which it closes the list); and “OMBREAK” (in response to which it reset and wait to accept a new connection).

[0073] Described above and illustrated in the drawings are improved methods and apparatus for process control. Those skilled in the art will appreciate that the embodiments discussed above and shown in the claims are merely illustrative and that other embodiments incorporating modifications within the reach of one of ordinary skill in the art fall within the scope of the invention, of which we claim:

1-48. (canceled)
49. A control system, comprising:
   a plurality of control system components in communications coupling with a network,
   at least one of the control system components being a service-providing component,
   the service-providing component providing one or more services in response to one or more messages from another of said control system components over the network, where those services include at least setting a value used by one or more control apparatus, at least one of which includes a control/sensing device, one or more interfaces, in communications coupling with the network and with the service-providing component, that facilitates invoking said services.
50. The control system of claim 49, wherein one or more of the interfaces is described in a document.
51. The control system of claim 49, wherein the network comprises any of an Internet, an enterprise-based Intranet, a LAN, WAN, cable television-based network, wireless network and/or telecommunications-based network.
52. The control system of claim 49, wherein the publicly available document describes (i) programmatic calls for invoking said services for any of accessing and updating information for the one or more control apparatus, and (ii) programmatic responses to such calls.
53. The control system of claim 49, wherein one or more of said messages comprises a request in text or ASCII format specifying object-related service.
54. The control system of claim 49, wherein one or more of the services permit manipulation of objects storing information pertaining to the one or more control apparatus.
55. The control system of claim 54, wherein one or more of the objects any of control and reflect the status of associated control apparatus.
56. The control system of claim 49, wherein the services include any of location service, a life cycle service, an access service, a connection service, a status service, and a notification service.
57. The control system of claim 49, wherein one of the components comprises a client digital data processor executing code supplied by another of the control system components.
58. The control system of claim 49, wherein at least the service-providing component disposed remotely from one or more other control system components.
59. The control system of claim 49, wherein the service-providing component executes on a server digital data processor.

60. The control system of claim 49, wherein the components include any of an HTTP server, a web browser, a client digital data processor and a server digital data processor.

61. The control system of claim 49, wherein the one or more processes include any of continuous, repetitive, discrete, and/or environmental control processes.

62. A control system, comprising:

first and second components in communications coupling over a network, each of the first and second components comprising software executing on respective processors,

the second component providing one or more services in response to one or more messages from the first component over the network, where those services include at least setting a value used by the one or more control apparatus, at least one of which includes a control/sensing device,

wherein one or more one or more messages comprises request in text or ASCII format.

63. A control system of claim 62, wherein the first and second components execute on processors that are disposed remotely from one another.

64. The control system of claim 62, comprising one or more interfaces, in communications coupling with the network and with the second component, that facilitates invoking said services.

65. The control system of claim 64, wherein one or more of the interfaces is described in a document.

66. The control system of claim 65, wherein the document describes (i) programmatic calls for invoking said services for any of accessing and updating information for the one or more control apparatus, and (ii) programmatic responses to such calls.

67. The control system of claim 62, wherein the network comprises any of an Internet, an enterprise-based Intranet, a LAN, WAN, cable television-based network, wireless network and/or telecommunications-based network.

68. The control system of claim 62, wherein one or more of the services permit manipulation of objects storing information pertaining to the one or more control apparatus.

69. The control system of claim 68, wherein one or more of the objects any of control and reflect the status of associated control apparatus.

70. The control system of claim 62, wherein the services include any of a location service, a life cycle service, an access service, a connection service, a status service, and a notification service.

71. The control system of claim 70, wherein the one or more services include a service for getting and/or setting a value associated with the one or more control apparatus.

72. The control system of claim 70, wherein the one or more services include a service for querying one or more of the process control apparatus for current data values associated therewith.

73. The control system of claim 70, wherein at least one of the one or more services comprise providing information about or a list of configurable values associated with the one or more control apparatus.

74. The control system of claim 62, wherein the first component comprises a client digital data processor executing code supplied by another of the control system components.

75. The control system of claim 62, comprising any of an HTTP server, a web browser, a client digital data processor and a server digital data processor.

76. A control system, comprising:

first and second digital data processors in communications coupling via one or more networks, where the one or more networks include any of an Internet, an Intranet, a LAN, WAN, cable television-based network, wireless network and/or telecommunications-based network, a first control component comprising software executing on the first digital data processor, a second control component comprising software executing on the second digital data processors, the second control component providing one or more services in response to one or more messages from the first component over the network, where those services include at least setting a value used by one or more control apparatus that includes a control/sensing device.

77. The control system of claim 76, wherein one or more one or more messages comprises request in text or ASCII format.

78. A control system of claim 76, wherein the first and second control components execute processors that are disposed remotely from one another.

79. The control system of claim 76, comprising a software interface that facilitates invoking said services.

80. The control system of claim 79, wherein the software interface is described in a document.

81. The control system of claim 80, wherein the document describes (i) programmatic calls for invoking said services for any of accessing and updating information for the one or more control apparatus, and (ii) programmatic responses to such calls.

82. The control system of claim 76, wherein one or more of the services permit manipulation of objects storing information pertaining to the one or more control apparatus.

83. The control system of claim 82, wherein one or more of the objects any of control and reflect the status of associated control apparatus.

84. The control system of claim 76, wherein the services include any of a location service, a life cycle service, an access service, a connection service, a status service, and a notification service.

85. The control system of claim 76, wherein the one or more services include a service for getting and/or setting a value associated with the one or more control apparatus.

86. The control system of claim 76, wherein the one or more services include a service for querying the one or more control apparatus for current data values associated therewith.

87. The control system of claim 76, wherein at least one of the one or more services comprise providing information about or a list of configurable values associated with the one or more control apparatus.

88. The control system of claim 76, comprising any of an HTTP server, a web browser, a client digital data processor and a server digital data processor.

89. A control system, comprising:

a plurality of control system components in communications coupling with a network, at least one of the control system components being a service-providing component providing services in
regard to objects storing information pertaining to one or more control apparatus, at least one of which includes a control/sensing device,
the service-providing component providing such services in response to one or more messages from another of said control system components over the network.
90. The control system of claim 89, comprising one or more interfaces coupled to the service-providing component that facilitate invoking said services.
91. The control system of claim 89, wherein one or more or more messages comprises request in text or ASCII format.
92. A control system of claim 89, wherein the first and second control components execute processors that are disposed remotely from one another.
93. The control system of claim 89, comprising a software interface that facilitates invoking said services.
94. The control system of claim 93, wherein the software interface is described in a document.
95. The control system of claim 94, wherein the document describes (i) programmatic calls for invoking said services for any of accessing and updating information for the one or more control apparatus, and (ii) programmatic responses to such calls.
96. The control system of claim 95, wherein one or more of the services permit manipulation of the objects.
97. The control system of claim 95, wherein one or more of the objects are control and reflect the status of associated control apparatus.
98. The control system of claim 95, wherein the services include any of a location service, a life cycle service, an access service, a connection service, a status service, and a notification service.
99. The control system of claim 95, wherein the services provide for (i) creating a named object that stores information regarding the one or more control apparatus, (ii) destroying such an object, (iii) accessing information in such an object, (iv) updating information in such an object, (v) determining, from an object name, a physical address associated with such an object, and (vi) providing notification of changes in at least selected information stored in such an object.
100. The control system of claim 95, wherein one of the components comprises a client digital data processor executing code supplied by another of the control system components.
101. The control system of claim 95, wherein the plurality of components includes any of an HTTP server, a web browser, a client digital data processor and a server digital data processor.
102. The control system of claim 100, wherein at least one of the plurality of components is included in a digital data processor.
103. The control system of claim 102, wherein the digital data processor comprises an HTTP server.
104. The control system of claim 102, wherein the digital data processor executes software that is responsive to said one or more messages exchanged via the network in text or ASCII form to provide the one or more services.
105. The control system of claim 100, wherein the network operates in accord with at least one of TCP/IP and HTTP protocol.
106. The control system of claim 100, wherein the one or more process control apparatus comprise control/sensing devices to any of monitor and control a process.
107. The control system of claim 100, comprising a digital data processor that generates said messages.
108. The control system of claim 107, wherein the digital data processor is disposed remotely from at least one of plurality of components.
109. The control system of claim 107, wherein the digital data processor comprises any of a portable computer, desktop computer, a personal digital assistant, workstation, or other computing system.
110. The control system of claim 107, wherein the digital data processor executes a code requested and received thereby over the network, the code configuring the digital data processor to generate said messages.
111. The control system of claim 100, wherein at least one of the plurality of components transfers information to and from the one or more process control apparatus in response to one or more of the messages.
112. The control system of claim 100, wherein the network includes at least one of a digital data processing network, LAN, WAN, cable television-based network, wireless network, telecommunications-based network, Internet, and an enterprise-based intranet.
113. The control system of claim 100, wherein the one or more services include a service for locating one or more objects that control or reflect the status of the one or more process control apparatus.
114. The control system of claim 100, wherein the one or more services include a service for any of (i) creating a named object that stores information regarding the process control apparatus, (ii) destroying such an object, (iii) accessing information in such an object, (iv) updating information in such an object, (v) determining, from an object name, a physical address associated with such an object, and (vi) providing notification of changes in at least selected information stored in such an object.
115. The control system of claim 100, wherein the one or more services include any of a life cycle service, an access service, a connection service, a status service, a location service, and a notification service.
116. The control system of claim 100, wherein one or more of the plurality of components comprises a server, and further comprising a second digital data processor that comprises a client and generates said messages.
117. The control system of claim 100, wherein the one or more services include a service for getting and/or setting a value associated with one or more of the process control apparatus.
118. The control system of claim 100, wherein the one or more services include a service for querying one or more of the process control apparatus for current data values associated therewith.

119. The control system of claim 100, wherein at least one of the one or more services comprise providing information about or a list of configurable values associated with one or more process control apparatus.

120. A method for process control, comprising:

- providing one or more services for at least setting information regarding one or more process control apparatus in a process control system, the one or more services being provided over a network;
- responding to requests received in text or ASCII form over the network to provide the one or more services.

121. The method of claim 120, comprising transmitting code that configures a digital data processor to generate and send the requests over the network.

122. The method of claim 120, comprising operating the network in accord with at least one of TCP/IP and HTTP protocols.

123. The method of claim 120, comprising monitoring and/or controlling the process control apparatus via the one or more services.

124. The method of claim 120, wherein the one or more services include a service for at least one of (i) creating a named object that stores information regarding the process control apparatus, (ii) destroying such an object, (iii) accessing information in such an object, (iv) updating information in such an object, (v) determining, from an object name, a physical address associated with such an object, and (vi) providing notification of changes in at least selected information stored in such an object.

125. A control system, comprising:

- a plurality of control system components in communications coupling via a network,
- at least a first one of the control system components providing one or more services to at least a second one of the control system components in response to one or more messages from that second component over the network, where those services include configuring the first component to any of (i) establish communications over the network with a third one of the control system components, (ii) to monitor and/or control said third component.

126. A control system of claim 49, wherein the services include setting a value relating to the third component.

127. A control system, comprising:

- a plurality of control system components in communications coupling via a network,
- at least a first one of the control system components providing one or more services to at least a second one of the control system components in response to one or more messages from that second component over the network, where those services include configuring the first component to access or update one or more objects that any of control and reflect a status of an associated process control apparatus.

128. A control system, comprising:

- A. a plurality of control system components in communications coupling via an IP network,
- B. at least a first control system component providing one or more services via the IP network to at least a second control system component, and
- C. wherein the one or more services include enabling the second component to locate an object in the control system, the object being associated with a third control system component.

129. The control system of claim 128, wherein the third component comprises any of control/sensing devices and interface equipment for control/sensing devices.

130. The control system of claim 128, wherein the third component comprises one or more devices and/or equipment to monitor and control processes.

131. The control system of claim 128, wherein the processes include any of continuous, repetitive and discrete processes, and environmental control processes.

132. The control system of claim 128, wherein the one or more services include enabling the second component to locate the object in a fourth control system component.

133. The control system of claim 132, wherein the fourth control system components comprises a control station.

134. A control system, comprising:

- A. a plurality of control system components in communications coupling via an IP network,
- B. at least a first control system component providing one or more services via the IP network to at least a second control system component, the one or more services enabling the second component to set a value associated with a third one of the control system components.

135. The control system of claim 134, wherein the value associated with the third component is included in an object.

136. The control system of claim 134, wherein the third component comprises any of control/sensing devices and interface equipment for control/sensing devices.

137. The control system of claim 134, wherein the third component comprises one or more devices and/or equipment to monitor and control processes.

138. The control system of claim 134, wherein the processes include any of continuous, repetitive and discrete processes, and environmental control processes.

139. The control system of claim 134, wherein the one or more services includes notifying the second component of changes related to the third component.

140. The control system of claim 134, wherein the one or more services include enabling the second component to set the value in an object in a fourth control system component.

141. The control system of claim 140, wherein the fourth control system components comprises a control station.

142. A control system, comprising:

- A. a plurality of control system components in communications coupling via an IP network,
- B. at least a first control system component providing one or more services via the IP network to at least a second control system component, the one or more services enabling a second component to register one or more characteristics for use by a third control system component over the network.

143. The control system of claim 142, wherein the one or more services include enabling the second component to register at least a name of an object.

144. The control system of claim 143, wherein the object stores information that any of controls and reflects a status of a fourth control system component.

145. The control system of claim 144, wherein the fourth component comprises any of control/sensing devices and interface equipment for control/sensing devices.

146. The control system of claim 143, wherein the second component comprises a control station.
147. The control system of claim 142, wherein the one or more services include enabling the third component to locate an object by name.

148. The control system of claim 147, wherein the object stores information that any of controls and reflects a status of a fourth control system component.

149. The control system of claim 148, wherein the fourth component comprises any of control/sensing devices and interface equipment for control/sensing devices.

150. The control system of claim 148, wherein the fourth component comprises one or more devices and/or equipment to monitor and control processes.

151. The control system of claim 150, wherein the processes include any of continuous, repetitive and discrete processes, and environmental control processes.
