ABSTRACT:

Inclusion of fatty adjuvants in vaccine compositions can cause difficulties with certain antigenic components, particularly with antigens that include a surfactant component. A method for preparing an immunogenic composition comprising an antigen and a fatty adjuvant involves purification of the antigen substantially in the absence of surfactant. Where surfactants cannot be avoided, the following are combined: (i) an antigen component that includes a surfactant and (ii) a fatty adjuvant component, to give a composition in which the weight ratio of said fatty adjuvant to said surfactant is less than 1000:1.

(54) Title: REDUCING INTERFERENCE BETWEEN OIL-CONTAINING ADJUVANTS AND SURFACTANT-CONTAINING ANTIGENS

(57) Abstract: Inclusion of fatty adjuvants in vaccine compositions can cause difficulties with certain antigenic components, particularly with antigens that include a surfactant component. A method for preparing an immunogenic composition comprising an antigen and a fatty adjuvant involves purification of the antigen substantially in the absence of surfactant. Where surfactants cannot be avoided, the following are combined: (i) an antigen component that includes a surfactant and (ii) a fatty adjuvant component, to give a composition in which the weight ratio of said fatty adjuvant to said surfactant is less than 1000:1.
REDUCING INTERFERENCE BETWEEN OIL-CONTAINING ADJUVANTS AND SURFACTANT-CONTAINING ANTIGENS

The use of fatty adjuvants in a composition and, in a second aspect, the invention uses a at most a 1000-fold weight ratio with fatty composition.

This invention is in the field of manufacturing adjuvanted vaccines. In particular, it concerns the use of fatty adjuvants during the manufacture of vaccines based on surfactant-containing antigens.

The common feature of some alternatives to aluminium salts is the presence of a fatty component. For example, the MF59 adjuvant includes squalene (an oil), and MPL™ contains a deacylated form of monophosphoryl lipid A having multiple fatty acid chains attached to a di-glucosamine backbone.

The invention concerns the avoidance of interference that can occur between these fatty adjuvants and antigens that include a surfactant component.

The inventor has found that fatty adjuvants in vaccine compositions can be incompatible with antigens that include a surfactant component. In many situations, however, it remains desirable to combine a fatty adjuvant and an antigen/surfactant mixture, and it is an object of the invention to provide ways of avoiding the difficulties that can arise in doing so. It is a further object to provide processes for combining adjuvants and antigens, in which incompatibility is avoided.

To avoid these incompatibility problems when using antigens that are typically purified by using surfactants, a first aspect of the invention provides a process for preparing an immunogenic composition, wherein: (a) the composition comprises an antigen and a fatty adjuvant; and (b) the antigen is purified substantially in the absence of surfactant. By purifying the antigen by an alternative route that avoids the use of surfactant, any incompatibility with fatty adjuvants can be overcome.

Clinical, historical or regulatory reasons, however, it may not be possible to purify an antigen without the use of surfactants, or to totally remove surfactants from vaccines. In this situation, the invention avoids interference by reducing the ratio of oil to surfactant in the composition. A typical MF59/HBsAg vaccine contains a huge excess of oil relative to surfactant, with an oil/surfactant ratio of over 4000:1 (by weight). The invention aims to minimise the amount of fatty adjuvant in a composition and, in a second aspect, the invention uses at most a 1000-fold weight...
excess of oil. Thus the invention provides a process for preparing an immunogenic composition, comprising the steps of combining (i) an antigen component that includes a surfactant and (ii) a fatty adjuvant component, to give a composition in which the weight ratio of the fatty adjuvant to the surfactant is less than 1000:1. Similarly, the invention provides an immunogenic composition, wherein: (a) the composition comprises an antigen component and a fatty adjuvant component; (b) the antigen component includes a surfactant; and (c) the weight ratio of the fatty adjuvant to the surfactant is less than 1000:1.

The fatty adjuvant

Aspects of the invention both utilise a fatty adjuvant i.e. an adjuvant component that includes a fatty molecule. Typical fatty adjuvants comprise a metabolisable oil, a fatty acid and/or a molecule comprising a fatty acid moiety.

Two preferred fatty adjuvants are the adjuvants known as 'MF59' and 'MPL'. 'MF59' is a fatty adjuvant because it contains squalene, which is a metabolisable oil. 'MPL' is a fatty adjuvant because it contains a disaccharide substituted with multiple fatty acid chains. As well as MF59, other oil-in-water emulsion adjuvants can also be used.

In addition to 'MF59' and 'MPL', other fatty adjuvants that can be used with the invention include, but are not limited to: glucosaminide phosphate derivatives; N-acyl-peptidomethionine; the soluble adjuvant derived from Escherichia coli lipid A known as 'OM-174'; compounds containing lipids linked to a phosphate-containing acyclic backbone; and acyclic synthetic lipid A analogs.

Where an oil-in-water emulsion adjuvant such as MF59 is used, it is typically added to an equal volume of an aqueous antigen composition, such that the emulsion is 50% by volume of the total composition. Where a 3D-MPL adjuvant is used, a typical dose is between 25µg/ml and 200µg/ml e.g. in the range 50-150µg/ml, 75-125µg/ml, 90-110µg/ml, or about 100µg/ml. It is usual to administer between 25-75µg of 3D-MPL per dose e.g. between 45-55µg, or about 50µg 3D-MPL per dose. An emulsion adjuvant such as MF59 will typically be provided in a separate container from the antigen, for extemporaneous mixing at the time of use, or it can be provided already admixed with the antigen. A 3D-MPL adjuvant will typically be already admixed with the antigen before distribution to end users.

MF59

The 'Mp59' adjuvant is an oil-in-water emulsion formed from squalene, Tween 80 (polyoxyethylene sorbitan monooleate) and Span 85 (sorbitan trioleate). The emulsion is microfluidised to give an emulsion with a submicron droplet size. Preparation of MF59 was
originally described in reference 3, and the product has been manufactured and sold by Chiron Corporation. Further details can be found in Chapter 10 of ref. 2, Chapter 12 of ref. 1 and in references 4 to 6. The composition of MF59 by volume is 5% squalene, 0.5% polysorbate 80 and 0.5% Span 85. In weight terms, these ratios become 4.3% squalene, 0.5% polysorbate 80 and 0.48% Span 85. MF59’s own surfactant content is not taken into account when calculating the ratio of oil:surfactant in the second aspect of the invention, as the ratio is based on the surfactant content of the antigen.

\[ [\text{oil}]_{10}^{[5]} T_{ij} \text{MF59} \] emulsion advantageously includes citrate ions e.g. 10mM sodium citrate buffer.

Other oil-in-water emulsions

An alternative to the MF59 adjuvant, other oil-in-water emulsions can be used. Adjuvant emulsions typically include at least one oil and at least one surfactant, with the oil(s) and surfactant(s) being biodegradable (metabolisable) and biocompatible. The oil droplets in the emulsion are generally less than 5μm in diameter, typically with a sub-micron diameter. Small droplet sizes can be achieved with a microfluidiser to provide stable emulsions. Droplets with a size less than 220nm are preferred as they can be subjected to filter sterilization.

too\[1\] The emulsion ions can include oils such as those from an animal (such as fish) or vegetable source, rather than mineral oils. Sources for vegetable oils include nuts, seeds and grains. Peanut oil, soybean oil, coconut oil, and olive oil, the most commonly available, exemplify the nut oils. Jojoba oil can be used e.g. obtained from the jojoba bean. Seed oils include safflower oil, cottonseed oil, sunflower oil, sesame seed oil and the like. In the grain group, corn oil is the most readily available, but the oil of other cereal grains such as wheat, oats, rye, rice, teff, triticale and the like may also be used. 6-10 carbon fatty acid esters of glycerol and 1,2-propanediol, while not occurring naturally in seed oils, may be prepared by hydrolysis, separation and esterification of the appropriate materials starting from the nut and seed oils. Fats and oils from mammalian milk are metabolizable and may therefore be used in the practice of this invention. The procedures for separation, purification, saponification and other means necessary for obtaining pure oils from animal sources are well known in the art. Most fish contain metabolizable oils which may be readily recovered. For example, cod liver oil, shark liver oils, and whale oil such as spermaceti exemplify several of the fish oils which may be used herein. A number of branched chain oils are synthesized biochemically in 5-carbon isoprene units and are generally referred to as terpenoids. Shark liver oil contains a branched, unsaturated terpenoids known as squalene, 2,6,10,15,19,23-hexamethyl-2,6,10,14,18,22-tetracosahexaene, which is particularly preferred herein. Squalane, the saturated analog to squalene, is also a preferred oil. Fish oils, including squalene and squalane, are readily available from commercial sources or may be obtained by methods known in the art. Other preferred oils are the tocopherols (see below). Mixtures of oils can be used.

\[ [\text{oil}]_{10}^{[8]} u_{f_{ac}} t_{an} t_{b} \] can be classified by their ‘HLB’ (hydrophilic/lipophilic balance). Preferred surfactants of the invention have a HLB of at least 10, preferably at least 15, and more preferably at least 16. The invention can be used with surfactants including, but not limited to: the
polyoxyethylene sorbitan esters surfactants (commonly referred to as the Tweens), especially polysorbate 20 and polysorbate 80; copolymers of ethylene oxide (EO), propylene oxide (PO), and/or butylene oxide (BO), sold under the DOWFAX™ tradename, such as linear EO/PO block copolymers; octoxynols, which can vary in the number of repeating ethoxy (oxy-1,2-ethanediyl) groups, with octoxynol-9 (Triton X-100, or t-octylphenoxypolyethoxyethanol) being of particular interest; (octylophenoxy)polyethoxyethanol (IGEPAL CA-630/NP-40); phospholipids such as phosphatidylycholine (lecithin); polyoxyethylene fatty ethers derived from lauryl, cetyl, stearyl and oleyl alcohols (known as Brij surfactants), such as triethyleneglycol monolauryl ether (Brij 30); and sorbitan esters (commonly known as the SPANs), such as sorbitan trioleate (Span 85) and sorbitan monolaurate. Preferred surfactants for including in the emulsion are Tween 80 (polyoxyethylene sorbitan monooleate), Span 85 (sorbitan trioleate), lecithin and Triton X-100. Mixtures of surfactants can be used e.g. Tween 80/Span 85 mixtures, or Tween80/Triton-X100 mixtures.

Oil-in-water emulsion adjuvants useful with the invention include, but are not limited to:

- An emulsion of squalene, a tocopherol, and Tween 80. The emulsion may include phosphate buffered saline. It may also include Span 85 (e.g. at 1%) and/or lecithin. These emulsions may have from 2 to 10% squalene, from 2 to 10% tocopherol and from 0.3 to 3% Tween 80, and the weight ratio of squalene:tocopherol is preferably ≤ 1 as this provides a more stable emulsion. One such emulsion can be made by dissolving Tween 80 in PBS to give a 2% solution, then mixing 90ml of this solution with a mixture of (5g of DL-α-tocopherol and 5ml squalene), then microfluidising the mixture. The resulting emulsion may have submicron oil droplets e.g. with an average diameter of between 100 and 250nm, preferably about 180nm.

- An emulsion of squalene, a tocopherol, and a Triton detergent (e.g. Triton X-100).

- An emulsion of squalane, polysorbate 80 and poloxamer 401 ("Pluronic™ L121"). The emulsion can be formulated in phosphate buffered saline, pH 7.4. This emulsion is a useful delivery vehicle for muramyl dipeptides, and has been used with threonyl-MDP in the "SAF-I" adjuvant [7] (0.05-1% Thr-MDP, 5% squalane, 2.5% Pluronic L121 and 0.2% polysorbate 80). It can also be used without the Thr-MDP, as in the "AF" adjuvant [8] (5% squalane, 1.25% Pluronic L121 and 0.2% polysorbate 80). Microfluidisation is preferred.

- An emulsion having from 0.5-50% of an oil, 0.1-10% of a phospholipid, and 0.05-5% of a non-ionic surfactant. As described in reference 9, preferred phospholipid components are phosphatidylcholine, phosphatidylethanolamine, phosphatidylserine, phosphatidylinositol, phosphatidylglycerol, phosphatidic acid, sphingomyelin and cardiolipin. Submicron droplet sizes are advantageous.

- A submicron oil-in-water emulsion of a non-metabolisable oil (such as light mineral oil) and at least one surfactant (such as lecithin, Tween 80 or Span 80). Additives may be included, such as QuilA saponin, cholesterol, a saponin-lipophile conjugate (such as GPI-0100, described in reference 10, produced by addition of aliphatic amine to desacylsaponin via the carboxyl group.
of glucuronic acid), dimethyldioctadecylammonium bromide and/or N,N-dioctadecyl-N,N-bis (2-hydroxyethyl)propanediamine.

- An emulsion in which a saponin (e.g. QuilA or QS21) and a sterol (e.g. a cholesterol) are associated as helical micelles [H].

The emulsions are preferably mixed with antigen extemporaneously, at the time of delivery. Thus the adjuvant and antigen are typically kept separately in a packaged or distributed vaccine, ready for final formulation at the time of use. The antigen will generally be in an aqueous form, such that the vaccine is finally prepared by mixing two liquids. The volume ratio of the two liquids for mixing can vary (e.g. between 5:1 and 1:5) but is generally about 1:1.

Where a composition includes a tocopherol, any of the α, β, γ, δ, ε or ξ tocopherols can be used, but α-tocopherols are preferred. The tocopherol can take several forms e.g. different salts and/or isomers. Salts include organic salts, such as succinate, acetate, nicotinate, etc. D-α-tocopherol and DL-α-tocopherol can both be used. A preferred α-tocopherol is DL-α-tocopherol, and the preferred salt of this tocopherol is the succinate.

3D-MPL

3Q-deacylated monophosphoryl lipid A (3D-MPL; also referred to as 3 de-O-acylated monophosphoryl lipid A or 3-O-desacyl-4'-monophosphoryl lipid A) is a known adjuvant. The name indicates that position 3 of the reducing end glucosamine in monophosphoryl lipid A is de-acylated. 3D-MPL has been prepared from a heptoseless mutant of Salmonella Minnesota, and is chemically similar to lipid A but lacks an acid-labile phosphoryl group and a base-labile acyl group. It activates cells of the monocyte/macrophage lineage and stimulates release of several cytokines, including IL-1, IL-12, TNF-α and GM-CSF. Preparation of 3D-MPL was originally described in reference 12, and the product has been manufactured and sold by Corixa Corporation under the trade name 'MPL'. Further details can be found in references 13 to 16.

3D-MPL can take the form of a mixture of related molecules, varying by their acylation (e.g. having 3, 4, 5 or 6 acyl chains, which may be of different lengths). The two glucosamine (also known as 2-deoxy-2-amino-glucose) monosaccharides are N-acylated at their 2-position carbons (i.e. at positions 2 and 2'), and there is also O-acylation at the 3' position. The group attached to carbon 2 has formula -NH-CO-CH₂-CR¹R⁴. The group attached to carbon 2' has formula -NH-CO-CH₂-CR³R². The group attached to carbon 3' has formula -O-CO-CH₂-CR³R². A representative structure is:
Groups $R^1$, $R^2$ and $R^3$ are each independently $-(CH_2)_n-CH_3$. The value of $n$ is preferably between 8 and 16, more preferably between 9 and 12, and is most preferably 10.

Groups $R^1$, $R^2'$ and $R^3'$ can each independently be: (a) -H; (b) -OH; or (c) -O-CO-$R^4$, where $R^4$ is either -H or $-(CH_2)_m-CH_3$, wherein the value of $m$ is preferably between 8 and 16, and is more preferably 10, 12 or 14. At the 2 position, $m$ is preferably 14. At the 2' position, $m$ is preferably 10. At the 3' position, $m$ is preferably 12. Groups $R^1$, $R^2'$ and $R^3'$ are thus preferably -O-acyl groups from dodecanoic acid, tetradecanoic acid or hexadecanoic acid.

When all of $R^1$, $R^2'$ and $R^3'$ are -H then the 3D-MPL has only 3 acyl chains (one on each of positions 2, 2' and 3'). When only two of $R^1$, $R^2'$ and $R^3'$ are -H then the 3D-MPL can have 4 acyl chains. When only one of $R^1$, $R^2'$ and $R^3'$ is -H then the 3D-MPL can have 5 acyl chains. When none of $R^1$, $R^2'$ and $R^3'$ is -H then the 3D-MPL can have 6 acyl chains. The 3D-MPL adjuvant used according to the invention can be a mixture of these forms, with from 3 to 6 acyl chains, but it is preferred to include 3D-MPL with 6 acyl chains in the mixture, and in particular to ensure that the hexaacyl chain form makes up at least 10% by weight of the total 3D-MPL e.g. >20%, >30%, >40%, >50% or more. 3D-MPL with 6 acyl chains has been found to be the most adjuvant-active form.

The preferred form of 3D-MPL for inclusion in compositions of the invention is:
[0028] Where 3D-MPL is used in the form of a mixture then references to amounts or concentrations of 3D-MPL in compositions of the invention refer to the combined 3D-MPL species in the mixture.

[0029] In aqueous conditions, 3D-MPL can form micellar aggregates or particles with different sizes e.g. with a diameter <150nm or >500nm. Either or both of these can be used with the invention, and the better particles can be selected by routine assay. Smaller particles (e.g. small enough to give a clear aqueous suspension of 3D-MPL) are preferred for use according to the invention because of their superior activity [17]. Preferred particles have a mean diameter less than 220nm, more preferably less than 200nm or less than 150nm or less than 120nm, and can even have a mean diameter less than 100nm. In most cases, however, the mean diameter will not be lower than 50nm. These particles are small enough to be suitable for filter sterilisation. Particle diameter can be assessed by the routine technique of dynamic light scattering, which reveals a mean particle diameter. Where a particle is said to have a diameter of x nm, there will generally be a distribution of particles about this mean, but at least 50% by number (e.g. >60%, >70%, >80%, >90%, or more) of the particles will have a diameter within the range x±25%.

[0030] The 3D-MPL can be used on its own as an adjuvant, or in combination with one or more further adjuvant compounds. For example, it is known to use 3D-MPL in combination with the QS21 saponin [18], with QS21 and an oil-in-water emulsion [19], with aluminium phosphate [20], with aluminium hydroxide [21], or with saponins & interleukin-12 [22].

[0031] A preferred adjuvant mixture, particularly for use with HBsAg, comprises a mixture of 3D-MPL and an aluminium salt, preferably aluminium phosphate. Advantageously, the 3D-MPL is adsorbed onto the aluminium salt. Preferably at least 50% (by weight) of the 3D-MPL is adsorbed e.g. >60%, >70%, >80%, >90%, >95%, >98% or more.

[0032] Aluminium adjuvants currently in use are typically referred to either as "aluminium hydroxide" or as "aluminium phosphate" adjuvants. These are names of convenience, however, as neither is a precise description of the actual chemical compound which is present (e.g. see chapter 9 of reference 2). For combination with a fatty adjuvant such as 3D-MPL, the invention can use any of the "hydroxide" or "phosphate" salts that are in general use as adjuvants.

[0033] A preferred adjuvant mixture, particularly for use with HBsAg, comprises a mixture of 3D-MPL and an aluminium salt, preferably aluminium phosphate. Advantageously, the 3D-MPL is adsorbed onto the aluminium salt. Preferably at least 50% (by weight) of the 3D-MPL is adsorbed e.g. >60%, >70%, >80%, >90%, >95%, >98% or more.

[0034] A preferred adjuvant mixture, particularly for use with HBsAg, comprises a mixture of 3D-MPL and an aluminium salt, preferably aluminium phosphate. Advantageously, the 3D-MPL is adsorbed onto the aluminium salt. Preferably at least 50% (by weight) of the 3D-MPL is adsorbed e.g. >60%, >70%, >80%, >90%, >95%, >98% or more.
groups. For example, an IR spectrum band at 3164 cm\(^{-1}\) (e.g. when heated to 200\(^{0}\)C) indicates the presence of structural hydroxyls (chapter 9 of ref. 2).

\[ \text{[0035]} \] \( T_{\mu} \) \( \beta \text{PO}_{4}^{2-} \text{Al}^{3+} \) molar ratio of an aluminium phosphate adjuvant will generally be between 0.3 and 1.2, preferably between 0.8 and 1.2, and more preferably 0.95+0.1. The aluminium phosphate will generally be amorphous, particularly for hydroxyphosphate salts. A typical adjuvant is amorphous aluminium hydroxyphosphate with \( \text{PO}_{4}^{2-} / \text{Al} \) molar ratio between 0.84 and 0.92, included at 0.6mg Al\(^{3+}\)-Aln. The aluminium phosphate will generally be particulate. Typical diameters of the particles are in the range 0.5-20\( \mu \)m (e.g. about 5-10\( \mu \)m) after any antigen adsorption.

\[ \text{[0036]} \] \( T_{\mu} \) e \( \beta \text{PZC} \) of aluminium phosphate is inversely related to the degree of substitution of phosphate for hydroxyl, and this degree of substitution can vary depending on reaction conditions and concentration of reactants used for preparing the salt by precipitation. PZC is also altered by changing the concentration of free phosphate ions in solution (more phosphate = more acidic PZC) or by adding a buffer such as a histidine buffer (makes PZC more basic). Aluminium phosphates used according to the invention will generally have a PZC of between 4.0 and 7.0, more preferably between 5.0 and 6.5 e.g. about 5.7.

\[ \text{[0037]} \] \( A_{n} \) aluminium phosphate solution used to prepare a composition of the invention may contain a buffer (e.g. a phosphate or a histidine or a Tris buffer), but this is not always necessary. The aluminium phosphate solution is preferably sterile and pyrogen-free. The aluminium phosphate solution may include free aqueous phosphate ions e.g. present at a concentration between 1.0 and 20 mM, preferably between 5 and 15 mM, and more preferably about 10 mM. The aluminium phosphate solution may also comprise sodium chloride. The concentration of sodium chloride is preferably in the range of 0.1 to 100 mg/ml (e.g. 0.5-50 mg/ml, 1-20 mg/ml, 2-10 mg/ml) and is more preferably about 3±1 mg/ml. The presence of NaCl facilitates the correct measurement of pH prior to adsorption of antigens.

\[ \text{[0038]} \] \( T_{\mu} \) \( \beta \) aluminium phosphate is preferably used in the form of an aqueous solution to which 3D-MPL (and, optionally, an antigen) is added (NB: it is standard to refer to aqueous aluminium phosphate as a "solution" although, on a strict physicochemical view, the salt is insoluble and forms a suspension). It is preferred to dilute the aluminium phosphate to the required concentration and to ensure a homogenous solution before the addition of the 3D-MPL and/or the antigen.

**N-acyl-pseudodipeptides**

\[ \text{[0039]} \] \( A \) N-acyl-pseudodipeptide adjuvant preferably includes a hydroxyl group that is esterified by an acid group in the neutral or charged form. The acyl groups give the pseudodipeptides a fatty character. The adjuvant preferably has formula (I):

\[
X\text{-A-(CH}_2\text{)}_m\text{-CH-(CH}_2\text{)}_n\text{-CO-NH-(CH}_2\text{)}_r\text{-CN-(CH}_2\text{)}_q\text{-B-Y}
\]

\[
\text{NHR}_1\text{NHR}_2
\]
where:
- \( R_1 \) is an acyl group derived from a saturated or unsaturated, straight or branched chain-
carboxylic acid having from 2 to 24 carbon atoms, the carboxylic acid being unsubstituted or
substituted with one or more substituents selected from the group consisting of hydroxyl, alkyl, alkoxy, acyloxy, amino, acylamino, acylthio and ((C\(_{1-4}\)alkyl)thio groups;

- \( R_2 \) is an acyl group derived from a saturated or unsaturated, straight or branched chain-
carboxylic acid having from 2 to 24 carbon atoms, the carboxylic acid being unsubstituted or
substituted with one or more substituents selected from the group consisting of hydroxyl, alkyl, alkoxy, acyloxy, amino, acylamino, acylthio and ((C\(_{1-4}\)alkyl)thio groups;

- \( X \) is a hydrogen atom or an acid group either in neutral or charged form;
- \( Y \) is a hydrogen atom or an acid group either in neutral or charged form;
- \( A \) is an oxygen atom, a sulfur atom or an imino group -NH-;
- \( B \) is an oxygen atom, a sulfur atom or an imino group -NH-;
- \( m \) is 1, 2, 3, 4, 5, 6, 7, 8, 9 or 10;
- \( n \) is 0, 1, 2, 3, 4, 5, 6, 7, 8, 9 or 10;
- \( p \) is 1, 2, 3, 4, 5, 6, 7, 8, 9 or 10; and
- \( q \) is 1, 2, 3, 4, 5, 6, 7, 8, 9 or 10,

provided that at least one of substituents \( X \) or \( Y \) designates an acid group in neutral or ionic form.

The adjuvant may be used either in acid or salt form, with an organic or mineral base.

Salt forming bases intended for therapeutic use mainly include alkaline metal bases such as
sodium, potassium or lithium hydroxides, ammonium salts; alkali earth metal bases such as calcium
or strontium hydroxide and magnesium salts; ferrous metal salts and the like; organic bases such as
those derived from primary, secondary, tertiary amines such as methylamine, diethylamine,
monoethanolamine, diethanolamine, benzylamine, N-methylbenzylamine, veratrylamine,
trimethoxybenzylamine; basic amino acids such as lysine and ornithine or amino sugars. Examples of
bases not intended for therapeutic use are brucine, strychnine, agmatine, homarine, glucosamine,
N-methylglucosamine or N-methylmorpholine.

Substituents \( X \) and \( Y \) are selected from:
- carboxy [(C\(^n\)alkyl]
- \( \text{CH}_2\text{[(CH}_{2}\text{)}_r\text{COOH}] \) [(CH\(_{2}\text{)}_s\text{COOH}]], where: \( r \) is 0, 1, 2, 3, 4 or 5; \( s \) is 0, 1, 2, 3, 4 or 5
- phosphono [(C\(_{1-5}\)alkyl]
- dihydroxyphosphoryloxy [(C\(_{3}\)alkyl]
- dimethoxyphosphoryl
- phosphono
- hydroxysulfonyl
- hydroxysulfonyl[(C₁₋₅)alkyl]
- hydroxysulfonyloxy [(C₁₋₅)alkyl]

[0043] Where substituents X and/or Y designate an acid group in neutral form, reference is made to the free carboxylic, sulfonic or phosphoric form. Where the acid group is in charged form, reference is made to the carboxylic, sulfonic or phosphoric salt form, namely by addition of an organic or mineral base, preferably one intended for therapeutic use. Similar considerations apply where X and/or Y designate a carboxylalkyl, alkenylbiscarboxylic, hydroxysulfonyl, hydroxysulfonylalkyl, hydroxysulfonloyxyalkyl, phosphonoalkyl, or a phosphoryl-oxyalkyl group.

When m=1 and n=0, the adjuvant derives from serine. When m=2 and n=0, the adjuvant derives from homoserine. If m=3 and n=0, reference is made to a pentahomoserine compound. If m=4 and n=0, reference is made to a hexahomoserine compound.

The product of interest may be a citrulline, ornithine or arginine compound. Where p=4 and q=l, reference is made to a homoarginine or lysine compound.

[0046] R₁ and R₂ include saturated or unsaturated, branched or straight chain, acyl derivatives having a variable size chain, of distinct or identical nature, which can have one or more substituents selected from the group consisting of alkyl, amino, acylamino, hydroxyl, alkoxy, acyloxy, acylthio and alkylthio groups.

[0047] Such acylated, substituted derivatives are ricinoleyl, 1,2-hydroxystearoyl, 2-hydroxy-3-methylbutyroyl, 3-hydroxy-2-aminopentanoyl, palmitoyl, elaidyl, eleostearoyl, arachidoyl, arachidonoyl, gadoleyl, behenyl, erucyl, 8-methyldecanoyl, 9-methyldecanoyl, docosohexaenoyl or eicosapentaneoyl radicals.

Adjuvants have formula (Ia), where A and B are both oxygen atoms:

\[
X-O-(CH_2)_m-CH-(CH_2)_n-CO-NH-(CH_2)_p-CH-(CH_2)_q-O-Y
\]

NHR₁    NHR₂

Adjuvants of formula (Ia) include:

- 3-(3-dodecanoyloxytetradecanoylamino) 9-(3-hydroxytetradecanoylamino) 4-oxo-5-azadecan-1,10-diol and/or 10-dihydrogenphosphate and its addition salts formed with an organic or a mineral base,

- 3-(3-dodecanoyloxy-tetradecanoylamino) 9-(3-hydroxytetradecanoylamino) 4-oxo-5-azadecan-1,10-diol 1,10-bis(dihydrogenphosphate) and its addition salts formed with an organic or a mineral base,
Methods for synthesising adjuvants of formula (I) are disclosed in detail in reference 23, and include methods comprising the steps of: protecting amine functional groups in positions (q+1) and ω of a diamino acid by blocking reagents which readily undergo acidolysis and hydrogolysis, respectively; reacting the free carboxylic functional group with a reducing agent to yield a corresponding alcohol; de-protecting the amine functional group in position (q+1) and then acylating by means of a carboxylic acid functional derivative of formula R₂OH, and subsequently freeing the terminal amine functional group by hydrogenolysis to yield a diamino alcohol of general formula II:

\[ \text{H}_2\text{N}-\text{CH}-\left(\text{CH}_2\right)_{q}\text{OH} \]

which amino alcohol is condensed in presence of a peptide condensing agent in an inert solvent, together with a ω-hydroxy, ω-amino or ω-thio amino acid compound of general formula III:

\[ \text{XA}-\left(\text{CH}_2\right)_{m}\text{-CH}-\left(\text{CH}_2\right)_{n}\text{-COOH} \]

\[ \text{NHR}_1 \]

\[ (m) \]

to provide a dipeptide compound of formula (IV):

\[ \text{XA}-\left(\text{CH}_2\right)_{m}\text{-CH}-\left(\text{CH}_2\right)_{n}\text{-CONH}\left(\text{CH}_2\right)_{p}\text{-CH}\left(\text{CH}_2\right)_{q}\text{-OH} \]

\[ \text{NHR}_1 \text{ NHR}_2 \]

\[ (IV) \]

the terminal free alcohol functional group of which can be, if necessary, protected (e.g. by an alkyl or acyl group, or any other suitable protecting group) or otherwise substituted, if needed, in presence of a coupling agent. The protected alcohol may be subjected to a catalytic hydrogenation or other de-protection treatment in order to obtain the derivative of general formula I.
Methods for synthesising adjuvants of formula (II) are also disclosed in detail in reference 23, and include methods comprising the steps of: protecting amine functional groups in positions \((q+1)\) and \(\omega\) of a diamino acid of formula \(H_2N(CH_2)_pCH(NH_2)H_2(CH_2)_q+iCOOH\) by protecting reagents which readily undergo acidolysis and hydrogenolysis, respectively; reacting the free carboxylic functional group with a reducing agent to yield a corresponding alcohol, de-protecting the amine functional group in position \((q+1)\) and then acylating by means of a carboxylic acid functional derivative of formula \(R_2OH\), then de-protecting the terminal amine functional group by hydrogenolysis to obtain an amino alcohol of general formula II; which amino alcohol is condensed in presence of a peptide condensing agent in an inert solvent, together with an \(\omega\)-hydroxy amino acid functional derivative of general formula Ilia:

\[
\text{XO}-(\text{CH}_2)_m\text{CH}-(\text{CH}_2)_n\text{COOH}
\]

(IIia)

where \(X\) is dialkyloxy- or diaryloxy- phosphoryl radical of formula \((RO)_2P-O\) to give a peptide-like compound of formula IVa:

\[
(RO)_2\text{PO}-(\text{CH}_2)_m\text{CH}-(\text{CH}_2)_n\text{-CONH}-(\text{CH}_2)_p\text{CH}-(\text{CH}_2)_q\text{OH}
\]

(IVa)

where \(R\) is a radical which readily undergoes hydrogenolysis, the other alcohol functional group of which can be, if desired, phosphorylated by a phosphorylating agent in presence of a coupling agent, if needed. The protected alcohol may be subjected to a catalytic hydrogenation on one hand in order to de-protect the alcohol functional group optionally present on acyl group \(R_2\) and on the other, free the phosphate functional group and then de-protect through hydrogenolysis the second optionally present phosphate functional group, in order to obtain the derivative of general formula V:

\[
(\text{HO})_2\text{PO}-(\text{CH}_2)_m\text{CH}-(\text{CH}_2)_n\text{-CONH}-(\text{CH}_2)_p\text{CH}-(\text{CH}_2)_q\text{O-Y}
\]

(V)

and optionally performing the further step of salt formation by means of an organic or mineral base.

Stereochemistry of chiral centres of acylamino groups is determined by initially used amino acid configuration whereas stereochemistry of acylamino groups depends on initially used fatty acid configuration. One can start from a diamino acid having L or D configuration or of a racemic nature. One can start from a hydroxylated amino acid of L, D configuration or of a racemic mixture. All such stereoisomers or diastereoisomers are included in the scope of the invention.

Particularly preferred adjuvants, and notably mono- and bis-phosphorylated compounds, are those which are known as "OM-294-MP" (formula VI) and "OM-294-DP" (formula VII) [23]:

-12-
OM-174

OM-174 can be obtained through chemical synthesis, and retains a triacyl motif from lipid A. It is described in more detail in references 24-26. Reference 26 gives the formula of OM-174 as:

\[
\text{(VI) – OM-294-MP}
\]

OM-174 has a 1,4'-biphosphorylated \(\beta(1\rightarrow6)\)-linked diglucosamine backbone, as found in natural lipid A. OM-174 may be present in the form of aggregates with a micellar \(H_1\) structure \textit{i.e.} in which the lipid molecules are packed with their backbone on a cylindrical surface with the acyl chains directed inwards, with the cylinders themselves being hexagonally packed. A cubic phase may be absent. A \(H_n\) phase may also be absent.

Glucosaminide phosphate derivatives

Aminoalkyl glucosaminide phosphate (AGP) derivatives (\textit{e.g.} RC-529 [27,28]) are fatty adjuvants because of acyl chains. In general, these derivatives can have the following formula [29]:
wherein:

- **X** represents an oxygen or sulfur atom in either the axial or equatorial position;
- **Y** represents an oxygen atom or NH group;
- "n", "m", "p" and "q" are the same or different and are integers from 0 to 6;
- **R**₁, **R**₂, and **R**₃, which may be the same or different, are fatty acyl residues having from 1 to about 20 carbon atoms and where one of **R**₁, **R**₂ or **R**₃ is optionally hydrogen;
- **R**₄ and **R**₅ are the same or different and are hydrogen or methyl;
- **R**₆ and **R**₇ are the same or different and are hydrogen, hydroxy, alkoxy, phosphono, phosphonooxy, sulfo, sulfooxy, amino, mercapto, cyano, nitro, formyl or carboxy and esters and amides thereof;
- **R**₈ and **R**₉ are the same or different and are phosphono or hydrogen, with preferably at least one of **R**₈ and/or **R**₉ being phosphono.

The configuration of the 3' stereogenic centers to which the normal fatty acyl residues are attached is R or S, but preferably R. The stereochemistry of the carbon atoms to which **R**₄ or **R**₅ are attached can be R or S. All stereoisomers, both enantiomers and diastereomers, and mixtures thereof, are considered to fall within the scope of the subject invention. Suitable adjuvants include salts of these compounds.

The preferred AGP compound is 'RC-529', which can be prepared as described in ref. 30:
Acyclic synthetic lipid A analogs

[0060] A lipid A analog that can be used as an adjuvant in the compositions of the invention is ER-1 12022 [31], a phospholipid dimer connected via an acyclic backbone:

[0061] Each monomeric unit of ER-112022 contains 3 unique fatty groups that are bound indirectly to a phosphate diester. The fatty groups include a 10-carbon ether chain, an unsaturated 12-carbon acyloxy chain bound to the ether chain, and a 14-carbon, b-oxo-amide chain linked closer to the phosphodiester. Thus, the compound has 3 unique features compared with naturally occurring lipid A.
from *E. coli*: (i) ER-1 12022 is devoid of a cyclic carbohydrate backbone; (ii) second, the phosphates are phosphodiesters incorporated within the confines of the structural backbone, unlike the phosphoesters on *E. coli* lipid A; and (iii) the structure is symmetrical (six symmetrically organized fatty acids on a noncarbohydrate backbone).

[0062] The compounds include those with formula XIV, XV or XVI, or salts thereof:

as defined in reference 32, such as 'ER 803058', 'ER 803732', 'ER 804053', ER 804058', E R 804059', 'ER 804442', 'ER 804680', E R 804764', ER 803022 or 'ER 804057' e.g.:
Compounds containing lipids linked to a phosphate-containing acyclic backbone can also be used as adjuvants, such as the TLR4 antagonist E5564 [33,34]:

![Diagram]

(XIX)

**The surfactant**

[0063] The first aspect of the invention substantially avoids the use of surfactant during antigen purification, such that the surfactant is not found within the antigen component used in the invention. In the second aspect, however, surfactant is used, but at controlled levels relative to the fatty adjuvant.

[0064] Typically, the invention can be used with surfactants including, but not limited to: the polyoxyethylene sorbitan esters surfactants (commonly referred to as the Tweens), especially polysorbate 20 and polysorbate 80; copolymers of ethylene oxide (EO), propylene oxide (PO), and/or butylene oxide (BO), sold under the DOWFAX™ trade name, such as linear EO/PO block copolymers; octoxynols, which can vary in the number of repeating ethoxy (oxy-1,2-ethanediyl) groups, with octoxynol-9 (Triton X-100, or t-octylphenoxy-polyethoxylethanol) being of particular interest; (octyloxy)polyethylene glycol (IGEPAL CA-630/NP-40); polyoxyethylene fatty ethers derived from lauryl, cetyl, stearyl and oleyl alcohols (known as Brij surfactants), such as triethyleneglycol monolauryl ether (Brij 30); and sorbitan esters (commonly referred to as the SPANs), such as sorbitan trioleate (Span 85) and sorbitan monolaurate.

[0065] Thus preferred embodiments of the first aspect of the invention substantially avoid the use of these two non-ionic surfactants in particular, and preferably substantially avoid the use of any non-ionic surfactant. Similarly, preferred embodiments of the second aspect of the invention use an antigen component that comprises one of these two non-ionic surfactants.
The invention is particularly suitable for use with polysorbate 20. This surfactant has an established safety profile for administration to humans, including within vaccines.

Surfactants can be classified by their 'HLB' (hydrophilic/lipophilic balance). Preferred surfactants of the invention have a HLB of at least 10, preferably at least 15, and more preferably at least 16.

To avoid administering large doses of the surfactant to a patient, it is preferred that the concentration of the surfactant in the composition should be no more than 50µg/ml e.g. ≤40µg/ml, ≤35µg/ml, ≤30µg/ml, ≤25µg/ml, ≤20µg/ml, ≤15µg/ml, ≤10µg/ml, ≤5µg/ml, etc. A concentration of ≤20µg/ml is preferred.

The antigen

The second aspect of the invention, the antigen component includes a surfactant. Rather than being a simple mixture of antigen and surfactant, it is preferred that the antigen and surfactant should be in the form of a complex. Antigen/surfactant complexes include surfactant-stabilised liposomes containing antigen, and niosomes, which are vesicles formed from synthetic nonionic amphiphilic compounds. A preferred antigen/surfactant complex is a particulate hepatitis B surface antigen, purified in the presence of surfactant. Reference 35 describes how recombinant HBsAg particles can retain Tween 20 that was used during their purification (up to 25µg Tween 20 per 100µg HBsAg).

The preferred antigen for use with the second aspect of the invention is thus the surface antigen of hepatitis B virus (HBV), in the form of substantially-spherical particles (average diameter of about 20nm), including a lipid matrix comprising both phospholipids and a non-ionic surfactant, such as polysorbate 20. Non-ionic surfactant can be incorporated into the particle during purification.

Hepatitis B virus (HBV) is one of the known agents which causes viral hepatitis. The HBV virion consists of an inner core surrounded by an outer protein coat or capsid, and the viral core contains the viral DNA genome. The major component of the capsid is a protein known as HBV surface antigen or, more commonly, 'HBsAg', which is typically a 226-amino acid polypeptide with a molecular weight of ~24 kDa. All existing hepatitis B vaccines contain HBsAg, and when this antigen is administered to a normal vaccinee it stimulates the production of anti-HBsAg antibodies which protect against HBV infection.
For vaccine manufacture, HBsAg can be made in two ways. The first method involves purifying the antigen in particulate form from the plasma of chronic hepatitis B carriers, as large quantities of HBsAg are synthesized in the liver and released into the blood stream during an HBV infection. The second way involves expressing the protein by recombinant DNA methods. HBsAg for use with the method of the invention is recombinantly expressed in yeast cells. Suitable yeasts include Saccharomyces (such as S. cerevisiae), Pichia (such as P. pastoris) or Hanensula (such as H. polymorpha) hosts. As an alternative, the antigen can be expressed in recombinant mammalian (e.g. in Chinese hamster ovary (CHO). COS cells, Bu3 cells, etc.), insect (e.g. using baculovirus vectors), or plant cells. In general, however, yeast expression is used.

The yeast-expressed HBsAg is preferably non-glycosylated. Unlike native HBsAg (i.e. as in the plasma-purified product), yeast-expressed HBsAg is generally non-glycosylated, and this is the most preferred form of HBsAg for use with the invention, because it is highly immunogenic and can be prepared without the risk of blood product contamination. Yeast-expressed HBsAg particles may include phosphatidylinositol, which is not found in natural HBV virions. The particles may also include a non-toxic amount of LPS in order to stimulate the immune system [36].

Many methods for purifying HBsAg are known in the art (e.g. see refs 37-62. Of these various processes, the first aspect of the invention uses one in which a non-ionic surfactant is not used. In contrast, the second aspect of the invention uses a non-ionic surfactant during purification, such that surfactant becomes incorporated into the final particulate HBsAg product. Using polysorbate 20 during disruption of recombinant yeast cells at the start of purification is a preferred way to introduce the surfactant into the HBsAg particles.

A preferred method for HBsAg purification involves, after cell disruption: ultrafiltration; size exclusion chromatography; anion exchange chromatography; ultracentrifugation; desalting; and sterile filtration. Lysates may be precipitated after cell disruption (e.g. using a polyethylene glycol), leaving HBsAg in solution, ready for ultrafiltration. Before or after the sterile filtration, it is possible to stabilise HBsAg particles by treatment with formaldehyde. Excess formaldehyde can then be removed by ultrafiltration or by chromatography. Further sterile filtration may be used.

The HBsAg is preferably from HBV subtype adw2.

A retroviridae protein. Retroviridae include lentiviruses and spumaviruses. Viruses of interest include HTLV-I, HTLV-II, feline immunodeficiency virus (FFV), human immunodeficiency virus (HIV, including HIV-I and HIV-2), simian immunodeficiency virus (SIV), chimpanzee foamy virus and human spumavirus.
- A paramyxoviridae protein, such as the F protein. Paramyxoviridae include (a) the Paramyxovirinae, which includes Paramyxoviruses, Rubulaviruses and Morbilliviruses and (b) the Pneumovirinae, which includes the Pneumoviruses. Viruses of interest include parainfluenza virus (PIV), human paramyxovirus, Rinderpest virus, Peste Des Petits Ruminants virus, Measles virus, Mumps virus, respiratory syncytial virus (RSV), Nipah Virus, Hendra Virus, Equine Morbillivirus (EMV), Lyssavirus and Menangle virus.

- A filoviridae protein. Filoviridae include the Marburg and Ebola viruses.

- A spike glycoproteins of a coronaviridae. Coronaviridae include coronaviruses and toroviruses. Viruses of interest include the human coronaviruses (including the SARS coronavirus), Avian infectious bronchitis virus, Feline infectious peritonitis virus, Murine hepatitis virus, Porcine epidemic diarrhea virus, Porcine hemagglutinating encephalomyelitis virus, Porcine transmissible gastroenteritis virus, and Berne virus.

- A rhabdoviridae protein, such as the G protein. Rhabdoviridae include Rabdoviruses, Vesiculoviruses, Lyssaviruses, Ephemeroviruses, Cytorhabdoviruses and Nucleorhabdoviruses. Viruses of interest include vesicular stomatitis virus, rabies virus, mokola virus, bovine ephemeral fever virus.

- A togaviridae protein. Togaviridae include Alphaviruses and Rubiviruses. Viruses of interest include Sindbis virus, Eastern and Western encephalitis viruses, Semliki Forest virus, rubella virus, Aura virus, Babanki virus, Barmah Forest virus avis-A, bebaru virus, Buggy Creek virus, chikungunya virus, Everglades virus, Fort Morgan virus, getah virus, Highlands J virus, Kyzylagach virus, Mayaro virus, Middelburg virus, Mucambo virus, Nduvu virus, Ockelbo virus, o'nyong-nyong virus, Pixuna virus, Ross River virus, Sagiyama virus, Una virus, Venezuelan equine encephalitis virus, and Whataroa virus.

- An envelope (E') glycoprotein of a flaviviridae. Flaviviridae include Flaviviruses, Pestiviruses and Hepaciviruses. Viruses of interest include dengue virus, hepatitis C virus, yellow fever virus, Japanese encephalitis virus, west nile virus, St. Louis encephalitis virus, bovine diarrhea virus and tick-borne encephalitis (TBE) virus.

- A bunyaviridae protein. Bunyaviridae include Bunyaviruses, Nairoviruses, Phleboviruses, Hantaviruses, and Tospoviruses. Viruses of interest include bunyavirus, Bunyamwera virus, California encephalitis virus, La Cross virus, Hantaan virus, Sin Nombre virus, Crimean-Congo hemorrhagic fever virus, Sandfly fever Sicilian virus and Rift valley fever virus.

- An arenaviridae protein. Arenaviridae include lymphocytic choriomeningitis virus, ippypox virus and lassa virus.

- A hepadnaviridae protein (including HBsAg). Hepadnaviridae include orthohepadnaviruses and avihepadnaviruses. As well as human hepatitis B virus, this viral family includes ground squirrel hepatitis B virus, woodchuck hepatitis B virus, woolly monkey hepatitis B virus, arctic squirrel hepatitis virus, duck hepatitis B virus, heron hepatitis B virus, and Ross' goose hepatitis B virus.
— A herpesviridae protein. Herpesviridae include Simplexviruses, Varicelloviruses, Roseoloviruses, Cytomegaloviruses, Muromegaloviruses, Lymphocryptoviruses and Rhadinoviruses. Viruses of interest include the human herpes viruses, including Herpes Simplex Viruses (HSV), Varicella-zoster virus (VZV), Epstein-Barr virus (EBV), Cytomegalovirus (CMV), Human Herpesvirus 6 (HHV6), Human Herpesvirus 7 (HHV7), and Human Herpesvirus 8 (HHV8), etc. Suitable antigens may be selected from glycoproteins gB, gC, gD and gH (e.g. in HSV). HSV gD2 is particularly preferred.

- An Orthomyxoviridae protein. Orthomyxoviridae include influenza virus and thogoto viruses. Antigens from influenza viruses are preferred (influenza A, B or C virus), including surface antigens hemagglutinin (HA) and/or neuraminidase (NA).

[0082] \( T_{\text{le}} \) \( \text{v}_{\text{ra}} \) \( \text{f}_{\text{ace}} \) antigens are typically purified by using surfactants, and so the antigen component can include a surfactant, particularly if present in a particulate form including lipids.

[0083] \( T_{\text{le}} \) \( \text{v}_{\text{ren}} \) \( \text{f}_{\text{on}} \) \( \text{s}_{\text{a}} \) \( \text{i}_{\text{o}} \) useful with particulate antigens based on hybrid or fusion proteins that comprise a viral surface antigen and a heterologous antigen. For instance, it is known to fuse the HBsAg sequence to heterologous antigens to exploit HBsAg’s ability to assemble into particles.

[0084] \( p_{\text{or}} \) example, reference 63 reports fusions of HIV-I gp120 to HBsAg to give a protein that spontaneously assembled into particles that resemble native HBsAg particles in size and density, consistent with a lipid composition of about 25% and a gp120 content of about 100 per particle. The gp120 was able to folds into its native conformation in the fusion, and retained its biological activity. Similarly, HIV gp41 epitopes have been improved by making internal fusions with HBsAg, and the fusion protein self-assembled in yeast into 22nm lipoprotein particles [64].

[0085] This approach has also been used for malaria vaccines. Reference 65 reports that epitopes of up to 61aa from the malaria gp190 antigen were inserted into the HBsAg sequence, and that the expressed hybrid particles could elicit an anti-gp190 immune response in animals. Reference 66 report an protein having 16 repeats of a 4-mer sequence of the circumsporozoite protein expressed as a fusion protein with HBsAg. Reference 67 reports the production in yeast of virus-like particles composed of Pfsl6 fused to HBsAg. Reference 68 discloses a hybrid antigen in which the circumsporozoite protein is fused to HBsAg. Reference 69 discloses a fusion of the C-terminal region of the merozoite surface 1 protein of P. vivax, which formed immunogenic particles of 20-45 nm size. The use of HBsAg for presenting malarial antigens in self-assembling particulate form is therefore well known in the art.

[0086] -p_{\text{le}} \text{in} \text{ven} tion can be used with hybrid antigens that comprise a viral surface antigen and a heterologous antigen. The heterologous antigen may be inserted into the viral surface antigen sequence, or may be fused to the N-terminus or C-terminus of the viral surface antigen sequence. If the native viral surface antigen can assemble into particles (e.g. HBsAg) then the insertion or fusion will not prevent this assembly.

-21-
hybrid proteins, the heterologous antigen may be from a bacterium, from a fungus, from a parasite, from a virus (but, by definition, the heterologous antigen is not HBsAg), etc. It is possible to include a complete heterologous antigen in the hybrid protein, but it is more usual to include an antigenic fragment of the antigen.

Particularly where the viral surface antigen is HBsAg, the heterologous antigen may be from HIV, *Plasmodium falciparum*, *Plasmodium vivax*, *Plasmodium malariae* or *Plasmodium ovale*. Suitable HIV antigens for making HBsAg hybrids include envelope glycoprotein gp120 or antigenic fragments thereof [63]. Suitable *P.falciparum* antigens for making HBsAg hybrids may be based on a subunit of the circumsporozoite surface antigen ("CSP") e.g. they may include between 3 and 20 repeats of its NANP motif (SEQ ID NO: 2), and/or they may include the C-terminal region of CSP (but typically not including the final 12 amino acids from the C-terminal). For example, the invention may use the antigen known as "RTS", which contains a large portion of the C-terminal of CSP from the NF54 or 7G8 isolate of *P.falciparum* (amino acids 210 to 398, which includes 19 NANP repeats and the T cell epitope region at amino acids 367 to 390), fused to the N-terminus of HBsAg by four amino acids of the preS2 portion of HBsAg. When expressed in yeast, RTS forms particles that include lipids (primarily phospholipid) in addition to protein. The sequence of RTS can thus contain: (i) a N-terminus methionine residue; (ii) Met-Ala-Pro; (iii) 189 amino acids corresponding either to amino acids 210-398 of CS protein from *P.falciparum* 7G8 or to amino acids 207-395 of CS protein from *P.falciparum* NF54; (iv) Arg or Gly; (v) Pro-Val-Thr-Asn from hepatitis B Pre-S2 protein; and (vi) HBsAg. From the 7G8 isolate, full-length RTS has the sequence given as SEQ ID NO: 1 in reference 70 (see also Figure 5 of reference 71):

![Sequence](https://example.com/sequence.png)

The heterologous antigen in yeast, using a sequence encoding SEQ ID NO:1. It is preferred to co-express the hybrid protein in yeast with normal HBsAg. This approach has previously been used with RTS, and the product of co-expression is referred to as "RTS,S". A RTS:S ratio of about 1:4 is useful. Expression in *S.cerevisiae* yeast is preferred, using a plasmid having a sequence encoding the hybrid protein, and including: (1) an upstream promoter from a glyceraldehyde-3-phosphate dehydrogenase gene, for controlling expression of the coding sequence; and (2) an ARG3 transcription terminator downstream of the coding sequence. The plasmids will also typically include: (3) a LEU2 selection marker; (4) a 2µ plasmid sequence; and (5) an origin of replication functional in *Escherichia coli*.

*RTS,S* may be combined with other malarial antigens, such as thrombospondin-related anonymous protein (TRAP). A preferred fatty adjuvant for use with *RTS,S* includes an oil-in-water emulsion, 3d-MPL and a QS-21 saponin.
Fatty adjuvant and surfactant ratio

According to the invention, the weight ratio in the composition of the fatty adjuvant to the antigen's surfactant is less than 1000:1.

For a composition containing 0.1 µg/ml surfactant in an antigen component, the squalene concentration will be less than 1000 µg/ml. For a composition containing 1 µg/ml surfactant in an antigen component, the squalene concentration will be less than 10 µg/ml. For a composition containing 100 µg/ml surfactant in an antigen component, the squalene concentration will be less than 1000 µg/ml.

An example of a composition containing 3D-MPL adjuvant and squalene is 1000:1 i.e. including all of the different acyl forms that may be present. For a composition containing 0.1 µg/ml surfactant in an antigen component, the total 3D-MPL concentration will be less than 100 µg/ml. For a composition containing 1 µg/ml surfactant in an antigen component, the total 3D-MPL concentration will be less than 100 µg/ml.

The 1000:1 ratio is a maximum. To further reduce the potential for interference between oil in an adjuvant and surfactant in an antigen, the ratio can be reduced. Thus the ratio may be <500:1, <400:1, <300:1, <200:1, <100:1, <50:1, or even <25:1. At a ≤100:1 ratio, a composition containing 1 µg/ml surfactant in an antigen component would have an oil content (e.g. squalene or 3D-MPL content) of <1 µg/ml. At a ≤25:1 ratio, a composition containing 100 µg/ml surfactant in an antigen component would have an oil content (e.g. squalene or 3D-MPL content) of ≤250 µg/ml; conversely, a composition comprising 100 µg/ml 3D-MPL would have no less than 4 µg/ml surfactant as part of the antigen.

The ratio is preferably greater than 1.5:1 e.g. >2:1, >2.5:1, >3:1, >4:1, ≥5:1 or more.

For 3D-MPL, a ratio between 2.5:1 and 25:1 is preferred, more preferably between 2.5:1 and 10:1, and even more preferably between 2.5:1 and 5:1. Thus a composition containing 10 µg/ml surfactant in an antigen component would have a 3D-MPL content of between 25 µg/ml and 250 µg/ml, preferably between 25 µg/ml and 100 µg/ml, and even more preferably between 25 µg/ml and 50 µg/ml; conversely, a composition comprising 100 µg/ml 3D-MPL would include an antigen having a surfactant content of between 4 µg/ml and 40 µg/ml, preferably between 10 µg/ml and 40 µg/ml, and even more preferably between 20 µg/ml and 40 µg/ml.

The immunogenic composition

A composition of the invention may comprise carriers, adjuvants, excipients, buffers, etc., as described in more detail below. These non-antigenic components may have various sources. For example, they may be present in one of the antigen or adjuvant materials that is used during manufacture or may be added separately from those components.
Preferred compositions of the invention include one or more pharmaceutical carrier(s) and/or excipient(s).

Tonicity, it is preferred to include a physiological salt, such as a sodium salt. Sodium chloride (NaCl) is preferred, which may be present at between 1 and 20 mg/ml.

Compositions will generally have an osmolality of between 200 mOsm/kg and 400 mOsm/kg, preferably between 240-360 mOsm/kg, and will more preferably fall within the range of 280-320 mOsm/kg. Osmolality has previously been reported not to have an impact on pain caused by vaccination [72], but keeping osmolality in this range is nevertheless preferred.

Compositions of the invention may include one or more buffers. Typical buffers include: a phosphate buffer; a Tris buffer; a borate buffer; a succinate buffer; a histidine buffer; or a citrate buffer. Buffers will typically be included in the 5-50mM range, and preferably in the 5-20mM range.

The pH of the invention will generally be between 5.0 and 7.5, and more typically between 5.0 and 6.0 for optimum stability, or between 6.0 and 7.0. The process of the invention may therefore include a step of adjusting the pH of the bulk vaccine prior to packaging into dosage containers. A vaccine containing diphtheria and tetanus toxoids preferably has a pH >6, to avoid the risk of toxicity reversion in the toxoids (particularly in the diphtheria toxoid), and thus a vaccine containing toxoids and HBsAg antigens preferably has a pH between 6.0 and 7.0. For other vaccines, including monovalent HBsAg vaccines, a pH <6 may be acceptable.

Compositions of the invention are preferably sterile.

Compositions of the invention are preferably non-pyrogenic e.g. containing <1 EU (endotoxin unit, a standard measure) per dose, and preferably <0.1 EU per dose.

If HBsAg is used, the final vaccine product may be a suspension with a cloudy appearance. This appearance means that microbial contamination is not readily visible, and so the vaccine preferably contains an antimicrobial agent. This is particularly important when the vaccine is packaged in multidose containers. Preferred preservatives for inclusion are 2-phenoxyethanol and/or thimerosal. It is recommended, however, not to use mercurial preservatives during the process of the invention, even though thimerosal is found in many existing HBV vaccines. For safety, however, it is preferred that the final composition contains less than about 25 ng/ml mercury. More preferably, the final vaccine product contains no detectable thimerosal. This will generally be achieved by removing the mercurial preservative from an antigen preparation prior to its addition in the process of the invention or by avoiding the use of thimerosal during the preparation of the components used to make the composition. HBsAg may be subjected to dialysis (e.g. with cysteine) to remove any mercurial preservatives such as thimerosal that may have been used during HBsAg preparation [73,74].
manufacture, dilution of components to give desired final concentrations will usually be performed with WFI (water for injection).

The concentration of any aluminium phosphate in a composition of the invention, expressed in terms of Al\(^{3+}\), is preferably less than 5 mg/ml e.g. \(\leq 4\) mg/ml, \(\leq 3\) mg/ml, \(\leq 2\) mg/ml, \(\leq 1\) mg/ml, etc.

The concentration of HBsAg in a composition of the invention is preferably less than 100 µg/ml e.g. \(\leq 90\) µg/ml, \(\leq 80\) µg/ml, \(\leq 70\) µg/ml, \(\leq 65\) µg/ml, \(\leq 60\) µg/ml, \(\leq 55\) µg/ml, \(\leq 50\) µg/ml, \(\leq 45\) µg/ml, \(\leq 40\) µg/ml, etc. A concentration of about 40 µg/ml or about 20 µg/ml is typical.

Compositions of the invention are preferably administered to patients in 0.5ml doses. References to 0.5ml doses will be understood to include normal variance e.g. 0.5ml±0.05ml.

The invention can provide bulk material which is suitable for packaging into individual doses, which can then be distributed for administration to patients. Concentrations mentioned above are typically concentrations in final packaged dose, and so concentrations in bulk vaccine may be higher (e.g. to be reduced to final concentrations by dilution).

Compositions of the invention will generally be in aqueous form.

Packaging compositions of the invention

After combining the antigen and adjuvant, the processes of the invention may comprise a step of extracting and packaging a 0.5ml sample of the mixture into a container. For multidose situations, multiple dose amounts will be extracted and packaged together in a single container. As mentioned above, in an alternative arrangement the antigen and adjuvant are packaged separately, for extemporaneous mixing at the point of use.

Processes of the invention may comprise the further step of packaging the vaccine into containers for use. Suitable containers include vials and disposable syringes (preferably sterile ones).

Where a composition of the invention is packaged into vials, these are preferably made of a glass or plastic material. The vial is preferably sterilized before the composition is added to it. To avoid problems with latex-sensitive patients, vials are preferably sealed with a latex-free stopper. The vial may include a single dose of vaccine, or it may include more than one dose (a 'multidose' vial) e.g. 10 doses. When using a multidose vial, each dose should be withdrawn with a sterile needle and syringe under strict aseptic conditions, taking care to avoid contaminating the vial contents. Preferred vials are made of colorless glass.

A vial can have a cap (e.g. a Luer lock) adapted such that a pre-filled syringe can be inserted into the cap, the contents of the syringe can be expelled into the vial, and the contents of the vial can be removed back into the syringe. After removal of the syringe from the vial, a needle can then be attached and the composition can be administered to a patient. The cap is preferably located inside a seal or cover, such that the seal or cover has to be removed before the cap can be accessed.
Where the composition is packaged into a syringe, which is preferred, the syringe will not normally have a needle attached to it, although a separate needle may be supplied with the syringe for assembly and use. Safety needles are preferred. 1-inch 23-gauge, 1-inch 25-gauge and 5/8-inch 25-gauge needles are typical. Syringes may be provided with peel-off labels on which the lot number and expiration date of the contents may be printed, to facilitate record keeping. The plunger in the syringe preferably has a stopper to prevent the plunger from being accidentally removed during aspiration. A rubber butyl plunger stopper is preferred. The syringes may have a latex rubber cap and/or plunger. Disposable syringes contain a single dose of vaccine. The syringe will generally have a tip cap to seal the tip prior to attachment of a needle, and the tip cap is preferably made of butyl rubber. If the syringe and needle are packaged separately then the needle is preferably fitted with a butyl rubber shield. Grey butyl rubber is preferred. Preferred syringes are those marketed under the trade name "Tip-Lok™."

Where a glass container (e.g. a syringe or a vial) is used, then it is preferred to use a container made from a borosilicate glass rather than from a soda lime glass.

After a composition is packaged into a container, the container can then be enclosed within a box for distribution e.g. inside a cardboard box, and the box will be labeled with details of the vaccine e.g. its trade name, a list of the antigens in the vaccine (e.g. 'hepatitis B recombinant', etc.), the presentation container (e.g. 'Disposable Prefilled Tip-Lok Syringes' or '10 x 0.5 ml Single-Dose Vials'), its dose (e.g. 'each containing one 0.5ml dose'), warnings (e.g. 'For Adult Use Only' or 'For Pediatric Use Only'), an expiration date, an indication (e.g. 'active immunisation against hepatitis B virus (HBV) infection caused by all known subtypes for patients with renal insufficiency (including pre-haemodialysis and haemodialysis) patients, from the age of 15 years onwards', etc.), a patent number, etc. Each box might contain more than one packaged vaccine e.g. five or ten packaged vaccines (particularly for vials). If the vaccine is contained in a syringe then the box may show a picture of the syringe.

The packaged vaccine is preferably stored at between 2°C and 8°C. It should not be frozen.

Methods of treatment and Administration of the vaccine

Compositions of the invention are suitable for administration to human patients, and the invention provides a method of raising an immune response in a patient, comprising the step of administering a composition of the invention to the patient.

The invention also provides a composition of the invention for use in medicine.
J1 invention provides the use of (i) an antigen purified substantially in the absence of surfactant and (ii) a fatty adjuvant, in the manufacture of a medicament for administering to a patient. The shaken composition will be a turbid white suspension.

The invention provides the use of (i) an antigen component that includes a surfactant and (ii) a fatty adjuvant, in the manufacture of a medicament for administering to a patient, wherein the weight ratio of the fatty adjuvant in (ii) to surfactant in (i) is less than 1000:1.

Immunogenic compositions of the invention are preferably vaccines e.g. for use in the prevention and/or treatment of hepatitis B virus infection. Patients who have received compositions of the invention preferably have a serum anti-HBsAg GM titer of >500 mIU/ml, measured 6 weeks after the first immunisation. More preferably, the titer is >500 mIU/ml, when measured after 12 months.

Compositions are particularly useful for protecting against and/or treating hepatitis B virus infections in patients for whom existing adjuvanted vaccines (such as the ENGERIX B™ product) are ineffective. Sub-groups of patients for whom the compositions are particularly suitable include: immunocompromised patients; hemodialysis patients; pre-hemodialysis patients; patients with renal insufficiency; patients with renal failure; patients with early renal failure before they require hemodialysis; patients awaiting liver transplantation e.g. on waiting lists; patients with end-stage renal failure; patients who have received an organ transplant (particularly a liver transplant) e.g. in the 6 month period preceding a first dose of the vaccine of the invention; patients who are receiving (or have been receiving e.g. in the 6 month period preceding a first dose of the vaccine of the invention) hepatitis B immunoglobulin (HBIg) treatment; patients with a HLA DQ2 haplotype [75]; patients with a HLA DR3 haplotype [75]; patients with a HLA DR7 haplotype [75]; patients with the with the HLA allele DQB 1*0202 [76]; patients infected with HIV; chronic HBV carriers; patients who have recently received a blood transfusion; patients receiving immunosuppressive drugs; patients suffering from AIDS; patients with ascites; patients with cirrhosis; patients with encephalopathy; patients receiving interferon therapy, and in particular ifn-α patients who smoke cigarettes; patients who smoke cigars; patients with a body mass index ³30 kg/m²; and patients who have received a HBsAg vaccine but who have not seroconverted (e.g. they have a serum anti-HBsAg titer of <10 mIU/ml after a standard primary dosing schedule, such as 3 doses of ENGERIX B™).

Patients may have a creatinine clearance rate of less than 30 ml/min (the normal healthy range being -100-140 ml/min in males and 90-130 ml/min in females). Patients are preferably at least 15 years old e.g. between 15-40 years, between 15-60 years, between 40-60 years, or even over 60. Patients aged over 55 can usefully be treated regardless of any underlying illness.

Compositions of the invention can be administered by intramuscular injection e.g. into the deltoid.

Where compositions of the invention include an aluminium-based adjuvant, settling of components may occur during storage. The composition should therefore be shaken prior to administration to a patient. The shaken composition will be a turbid white suspension.
Preferred processes and vaccines of the invention

A preferred process for preparing an immunogenic composition comprises the steps of combining (i) an HBsAg component that includes polysorbate 20 and (ii) an adjuvant component comprising 3D-MPL adsorbed to an aluminium phosphate, to give a composition in which the weight ratio of 3D-MPL to polysorbate 20 is less than 1000:1.

A preferred immunogenic composition is one wherein: (a) the composition comprises HBsAg, polysorbate 20, 3D-MPL and an aluminium phosphate adjuvant; and (b) the weight ratio of the 3D-MPL to polysorbate 20 is less than 1000:1. The 3D-MPL and the HBsAg are preferably adsorbed to the aluminium phosphate. The HBsAg concentration is about 40µg/ml. The 3D-MPL concentration is about 100µg/ml. The Al3+ concentration is about 1µg/ml.

The composition of the invention comprises (i) HBsAg, purified from S.cerevisiae, and (ii) an adjuvant comprising a mixture of aluminium phosphate and 3D-MPL. The HBsAg concentration is about 40µg/ml. The 3D-MPL concentration is about 100µg/ml. The Al3+ concentration is about 1µg/ml. HBsAg includes polysorbate 20, and the oil:surfactant weight ratio (i.e. the 3D-MPL:polysorbate 20 weight ratio) is between 2.5:1 and 100:1 i.e. the polysorbate 20 is present at a level between 1µg/ml and 40µg/ml (i.e. between 2.5µg and 100µg polysorbate 20 per 100µg HBsAg). The ratio is preferably is between 2.5:1 and 25:1 i.e. the polysorbate 20 is present at a level between 4µg/ml and 40µg/ml. The 3D-MPL and the HBsAg are both adsorbed to the aluminium phosphate.

General

The term "comprising" X may consist exclusively of X or may include something additional e.g. X + Y.

The term "substantially" does not exclude "completely" e.g. a composition which is "substantially free" from Y may be completely free from Y. Where necessary, the word "substantially" may be omitted from the definition of the invention.

The term "about" in relation to a numerical value x means, for example, x±10%.

Specifically stated, a process comprising a step of mixing two or more components does not require any specific order of mixing. Thus components can be mixed in any order. Where there are three components then two components can be combined with each other, and then the combination may be combined with the third component, etc. As described above, components can be mixed during manufacture, or extemporaneously at the time of use.

Where an antigen is described as being "adsorbed" to an adjuvant, it is preferred that at least 50% (by weight) of that antigen is adsorbed e.g. 50%, 60%, 70%, 80%, 90%, 95%, 98% or more. It is preferred that HBsAg is totally adsorbed i.e. none is detectable in supernatant.

Where animal (and particularly bovine) materials are used in the culture of cells, they should be obtained from sources that are free from transmissible spongiform encephalopathies (TSEs), and in particular free from bovine spongiform encephalopathy (BSE).
But j j-e j g include chlorobutyl and bromobutyl rubbers.

It will be appreciated that ionisable groups may exist in the neutral form shown in formulae herein, or may exist in charged form e.g. depending on pH. Thus a phosphate group may be shown as -P-O-(OH)₂, this formula is merely representative of the neutral phosphate group, and other charged forms are encompassed by the invention. Similarly, sugar rings can exist in open and closed form and, while closed forms are shown in structural formulae herein, open forms are also encompassed by the invention.

MODES FOR CARRYING OUT THE INVENTION

Different HBsAg preparations were studied:

- HBsAg expressed in S.cerevisiae cells, purified using non-ionic surfactant.
- HBsAg expressed in Hanensula yeast cells, purified using non-ionic surfactant.
- HBsAg expressed in CHO cells, with preS2 sequence, purified without use of surfactants.

Different adjuvants were studied:

- Aluminium hydroxide (1 mg/ml)
- MF59 in citrate buffer (13 mM)

Formulations A to D were used to immunise African green monkeys. Groups of 6 monkeys were immunised intramuscularly on day 0 and day 28. Bleeding were taken at time 0 and then every 2 weeks till week 8, and anti-HBsAg titres (GMT) were measured by ELISA. Titres were normalised to 1.0, which was the day 14 value in each group, and the normalised results were as follows:

<table>
<thead>
<tr>
<th>Host</th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>Al Hydrox</td>
<td>CHO</td>
<td>CHO</td>
<td>Yeast</td>
<td>Yeast</td>
</tr>
<tr>
<td>MF59</td>
<td>Al Hydrox</td>
<td>MF59</td>
<td>Al Hydrox</td>
<td>MF59</td>
</tr>
<tr>
<td>Day 14</td>
<td>1.0</td>
<td>1.0</td>
<td>1.0</td>
<td>1.0</td>
</tr>
<tr>
<td>Day 28</td>
<td>0.9</td>
<td>0.8</td>
<td>1.3</td>
<td>0.4</td>
</tr>
<tr>
<td>Day 42</td>
<td>19.2</td>
<td>159.8</td>
<td>108.8</td>
<td>85.2</td>
</tr>
<tr>
<td>Day 56</td>
<td>10.8</td>
<td>32.6</td>
<td>61.3</td>
<td>24.5</td>
</tr>
</tbody>
</table>
Looking at the day 42 and day 56 titres, these data show that the MF59 adjuvant increased titres much more markedly than the aluminium adjuvant for CHO-expressed antigen (160-fold increase vs. 20-fold increase at day 42), but the situation was reversed for the Hanensula-expressed antigen (85-fold increase vs. 110-fold increase at day 42).

Similar experiments were performed in baboons, using formulations B, E and F. GMT values were measured 14 days after the first injection and, relative to the group F value, were as follows:

<table>
<thead>
<tr>
<th>Surfactant</th>
<th>A</th>
<th>B</th>
<th>E</th>
<th>F</th>
</tr>
</thead>
<tbody>
<tr>
<td>Adjuvant</td>
<td>Al Hydrox</td>
<td>MF59</td>
<td>Al Hydrox</td>
<td>MF59</td>
</tr>
<tr>
<td>Day 14</td>
<td>-</td>
<td>13.5</td>
<td>4.5</td>
<td>1.0</td>
</tr>
</tbody>
</table>

MF59 instead of the alum adjuvant leads to a lower GMT response (compare groups E and F), whereas an increase would be expected (group B and reference 77).

Anti-HBsAg responses 28 days after first injection using formulations E and F were also compared in rhesus monkeys, african green monkeys and C3H mice (NB: mice received 60% of the FIBsAg dose). As well as measuring GMT values, the number of responders was also measured i.e. animals showing a titre of >10mIU/ml. Results, normalised to group F, were as follows:

<table>
<thead>
<tr>
<th>GMT</th>
<th>Responders</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>E</td>
</tr>
<tr>
<td>Adjuvant</td>
<td>Al Hydrox</td>
</tr>
<tr>
<td>Rhesus</td>
<td>4.2</td>
</tr>
<tr>
<td>AGM</td>
<td>110.0</td>
</tr>
<tr>
<td>Mice</td>
<td>0.1</td>
</tr>
</tbody>
</table>

Therefore, using MF59 as the adjuvant in primates resulted in a substantial decrease both in GMT values and in responder levels for the S.cerevisiae-expressed HBsAg.

Finally, the increase in GMT resulting from booster vaccination with formulations E and F was measured in seropositive african green monkeys. Titres were measured before the booster dose and then again 28 days later, and the increase in titres was as follows:

<table>
<thead>
<tr>
<th>Group</th>
<th>Adjuvant</th>
<th>Increase (x)</th>
</tr>
</thead>
<tbody>
<tr>
<td>E</td>
<td>Al Hydrox</td>
<td>91.5 x</td>
</tr>
<tr>
<td>F</td>
<td>MF59</td>
<td>19.1 x</td>
</tr>
</tbody>
</table>

Overall, therefore, MF59 seems to be a worse adjuvant than aluminium hydroxide for yeast-expressed HBsAg in primates, but a better adjuvant for CHO-expressed HBsAg. These results may be explained by an interaction between (a) residual surfactant in HBsAg purified from yeast and...
(b) excess squalene oil in the MF59 adjuvant. As an oil, squalene is subject to the action of surfactants in aqueous conditions, and *vice versa*, and it is proposed that the surfactant in the antigen is incompatible with the oil in the adjuvant. This incompatibility can be dealt with either by purifying the HBsAg without using detergents (e.g. as in the CHO-expressed material), or by ensuring that the oil is not present at such an excess that it interferes with the surfactant in the antigen.

[0154] In a MF59-adjuvanted HBsAg composition, one volume of MF59 is combined with one volume of antigen solution. In a 100ml volume, there will thus be 50ml MF59 and 50ml HBsAg solution. This 100ml contains 2.15g squalene from the MF59 and, at a HBsAg concentration of 40µg/ml, it contains 2mg HBsAg. At a polysorbate 20 concentration of 25µg per 100µg HBsAg [35], the 100ml contains 0.5mg polysorbate 20. The oil:surfactant ratio in a typical MF59-adjuvanted vaccine is thus 4300:1. By reducing the oil excess to be less than 1000:1, the interaction between oil in the adjuvant and surfactant in the antigen can be substantially reduced, thereby reducing interference.

[0155] It will be understood that the invention has been described by way of example only and modifications may be made whilst remaining within the scope and spirit of the invention.

1. A process for preparing an immunogenic composition, comprising the steps of combining (i) an antigen component that includes a surfactant and (ii) a fatty adjuvant component, to give a composition in which the weight ratio of the fatty adjuvant to the surfactant is less than 1000:1.

2. An immunogenic composition, wherein: (a) the composition comprises an antigen component and a fatty adjuvant component; (b) the antigen component includes a surfactant; and (c) the weight ratio of the fatty adjuvant to the surfactant is less than 1000:1.

3. The process or composition of claim 1 or claim 2, wherein the fatty adjuvant comprises a metabolisable oil.

4. The process or composition of claim 3, wherein the fatty adjuvant comprises a sub-micron oil-in-water emulsion of squalene and polysorbate 80.

5. The process or composition of claim 1 or claim 2, wherein the fatty adjuvant comprises a molecule comprising a fatty acid moiety.

6. The process or composition of claim 5, wherein the fatty adjuvant is a 3-deoxyacylated monophosphoryl lipid A (‘3D-MPL’).

7. The process or composition of claim 6, wherein the 3D-MPL is a mixture of molecules varying by their acylation.

8. The process or composition of claim 6 or claim 7, wherein the fatty adjuvant includes:
9. The process or composition of any one of claims 6 to 8, wherein the 3D-MPL is in the form of particles.

10. The process or composition of claim 9, wherein the particles can be filter sterilised.

11. The process or composition of any one of claims 6 to 10, wherein the 3D-MPL is in combination with an aluminium salt.

12. The process or composition of claim 11, wherein the aluminium salt is an aluminium phosphate.

13. The process or composition of claim 12, wherein the 3D-MPL is adsorbed onto the aluminium salt.

14. The process or composition of any preceding claim, wherein the surfactant is a polyoxyethylene sorbitan ester.

15. The process or composition of claim 14, wherein the ester is polysorbate 20.

16. The process or composition of claim 14 or claim 15, wherein the concentration of surfactant no more than 50 µg/ml.

17. The process or composition of any preceding claim, wherein the antigen is a viral surface antigen.

18. The process or composition of claim 17, wherein the antigen is a particulate hepatitis B surface antigen ('HBsAg'), purified in the presence of surfactant.

19. The process or composition of claim 18, wherein the HBsAg is expressed in a yeast cell.

20. The process or composition of claim 19, wherein the yeast is a *Saccharomyces cerevisiae*.

21. The process or composition of any one of claims 18 to 20, wherein the HBsAg is non-glycosylated and/or includes phosphatidylinositol.

22. The process or composition of any one of claims 18 to 21, wherein the HBsAg is from subtype adw2 of hepatitis B virus.

23. The process or composition of any preceding claim, wherein the antigen is a hybrid protein comprising a viral surface antigen and a heterologous antigen.

24. The process or composition of claim 23, wherein the viral surface antigen is HBsAg and the heterologous antigen is a malaria antigen.

25. The process of composition of claim 24, wherein the hybrid protein comprises HBsAg and a fragment of the circumsporozoite protein of *Plasmodium falciparum*.

26. The process of composition of claim 25, wherein the hybrid protein comprises a C-terminal portion of a *P. falciparum* circumsporozoite protein of Plasmodium falciparum, four or more tandem repeats of the circumsporozoite protein immunodominant region, and HBsAg.

-34-
27. The process or composition of any preceding claim, wherein the weight ratio of the fatty adjuvant to the surfactant is less than 500:1.

28. The process or composition of any preceding claim, wherein the weight ratio of the fatty adjuvant to the surfactant is less than 50:1.

29. The process or composition of any preceding claim, wherein the weight ratio of the fatty adjuvant to the surfactant is less than 50:1.

30. The process or composition of any preceding claim, wherein the composition has a osmolality of between 200 mθ sm/kg and 400 mθ sm/kg.

31. The process or composition of any preceding claim, wherein the composition includes a phosphate buffer.

32. The process or composition of any preceding claim, wherein the composition has a pH between 6.0 and 7.0.

33. The use of (i) an antigen component that includes a surfactant and (ii) a fatty adjuvant, in the manufacture of a medicament for administering to a patient, wherein the weight ratio of the fatty adjuvant in (ii) to surfactant in (i) is less than 1000:1.

34. A process for preparing an immunogenic composition, comprising the steps of combining (i) an HBsAg component that includes polysorbate 20 and (ii) an adjuvant component comprising 3D-MPL adsorbed to an aluminium phosphate, to give a composition in which the weight ratio of 3D-MPL to polysorbate 20 is less than 1000:1.

35. An immunogenic composition, wherein: (a) the composition comprises HBsAg, polysorbate 20, 3D-MPL and an aluminium phosphate adjuvant; and (b) the weight ratio of the 3D-MPL to polysorbate 20 is less than 1000:1.

36. A process for preparing an immunogenic composition, wherein: (a) the composition comprises an antigen and a fatty adjuvant; and (b) the antigen is purified substantially in the absence of surfactant.
