ABSTRACT

A meal planning system includes memory having appliance user domain data and control system domain data. One or more instances of appliance user domain data are bound to one or more instances of control system domain data or one or more instances of other appliance user domain data. The appliance user domain data and the control system domain data are related to planning and preparing one or more meals. The system also has a communication path connected to the memory and connectable to a data sender. A query from the data sender to the memory over the communication path, and associated with criteria data referencing at least a portion of the control system domain data or the other appliance user domain data, will return data to the data sender so that the data sender can use the return data to affect the planning and preparing of a meal.

Is the shutoff valve turned on to allow water flow?

[Yes, No]

Fig. 11A
Fig. 12
Appliance 12

130 slow or no water dispensing

If the refrigerator was recently installed, make sure that it is connected to a water supply and the shutoff valve is fully turned on. Also confirm water flow through the valve is adequate. The 1/4" water supply line should deliver at least 9 ounces of water in 5 seconds. If not, the water pressure is low.

Fig. 13A
Appliance 2 is slow or no water dispensing

For questions regarding low water pressure contact a licensed plumber.

Saddle/shutoff valves are often located either behind the refrigerator or under the sink. Other locations include such places as the basement or crawl space.

Because we allow a byte to contain more than one message element it is possible to have a message element whose length does not fall on a byte boundary. For this reason, message element length is specified in bits (start counting at 1).
Often, a message contains data payload many parameters within its payload. Each parameter has its own meaning, and even its own validation. Creating a message data payload from multiple message elements allows the developer to specify in great detail all of the information associated with each element of a message data payload.
The value of the apiID attribute is 0, which is less than the minimum 1.

MEAL PLANNING AND PREPARATION SYSTEM

CROSS REFERENCE TO RELATED APPLICATIONS

[0001] This application is a continuation of PCT/US2009/
046186 filed Jun. 3, 2009, which claims priority from U.S.

FIELD OF THE INVENTION

[0002] The invention relates to a system for preparing and
planning meals in communication with an appliance.

DESCRIPTION OF THE RELATED ART

[0003] Household appliances typically comprise one or
more components responsible for the electromechanical
operations of the appliance. For example, an oven can include
an appliance management component having a printed circuit
board (PCB) with memory, as well as a user-interface com-
ponent, such as a control panel or keypad, for a user to issue
commands to the oven. As another example, a washing
machine can include an appliance management component, a
user-interface component, and a motor control component
that controls a motor of the washing machine.

[0004] Typically, discrete circuits couple the internal com-
ponents of an appliance, with each discrete circuit responsible
for individual communication between related components.
The circuits communicate with each other over an internal
network that traditionally is implemented by hard-wired ribbon
cables or other connectors or harnesses between the compo-
nents. The hard-wired connectors form a closed sys-
tem or network that is difficult or not possible to modify. For
example, because the closed network relies on hard-coded or
hard-wired network solutions, it is not practical to couple
additional external components or additional internal com-
nents to the appliance to expand the capability or function of
the appliance. The closed network cannot easily be adapted
for communication with the additional external/internal com-
mponents and therefore limits the potential of the appliance.

[0005] In some instances, service personnel can access the
interior of an appliance and connect an external device to the
internal network in order to modify the operation of or oth-
erwise interact with the internal components of the appliance.
However, scheduling appointments with service personnel
can be inconvenient, and accessing the interior of the appli-
cance can require the use of specialized tools and can poten-
tially damage the appliance in the process. In addition, due to
the limited potential of the internal components, the user of
the appliance is unable to thoroughly personalize the opera-
tion of the appliance in order to tailor the appliance to his or
her particular needs.

SUMMARY OF THE INVENTION

[0006] A meal planning system, according to the invention,
includes memory having appliance user domain data and
control system domain data. One or more instances of appli-
cance user domain data are bound to one or more instances
of control system domain data or one or more instances of other
appliance user domain data. The appliance user domain data
and the control system domain data are related to planning
and preparing one or more meals. The systems also has a
communication path connected to the memory and connect-
able to a data sender. With this fundamental structure, a query
associated with criteria data referencing at least a portion of
the control system domain data or the other appliance user
domain data from the data sender to the memory over the
communication path will return data to the data sender so that
the data sender can use the return data to affect the planning
and preparing of a meal.

BRIEF DESCRIPTION OF THE DRAWINGS

[0007] In the drawings:

[0008] FIG. 1 is a schematic diagram showing the environ-
ment of an appliance development toolkit according to the
invention.

[0009] FIG. 2 is a schematic diagram showing elements of
an appliance development toolkit according to the invention.

[0010] FIG. 3 is a schematic diagram showing relationships
among elements of the system configurator in the appliance
development toolkit of FIGS. 1 and 2.

[0011] FIG. 4 is a diagram showing the functional relation-
ship among some of the elements of FIG. 3.

[0012] FIG. 5 is a screen shot of an editor and a content
viewer of an appliance development toolkit according to the
invention.

[0013] FIG. 6A shows a first embodiment of a user interface

FIG. 48A illustrates a sequence model instance for recipes in FIG. 48. FIG. 48B illustrates a sequence model instance for substitutions in FIG. 48.

DESCRIPTION OF EMBODIMENTS OF THE INVENTION

Referring to the drawings and to FIG. 1 in particular, an appliance development toolkit 10 according to the invention, which will be referred to hereinafter as the toolkit 10, is configured to enable the creation and modification of content 20 to affect and/or effect operation of one or more components associated with an appliance 12 so as to affect and/or effect interaction between a user 14 and the appliance 12 and/or a cycle of operation of the appliance 12. The toolkit 10 can be used with different appliances 12 without requiring the recording of software of the toolkit 10. The user 14 can be a consumer, a salesperson, a manufacturer 14A (see FIG. 25), a
product engineer, or any other individual capable of using the appliance 12 and/or the toolkit 10.

[0064] The appliance 12 can be any suitable appliance, such as a household appliance. Examples of household appliances include, but are not limited to, clothes washing machines, clothes dryers, ovens, dishwashers, refrigerators, freezers, microwave ovens, trash compactors, and countertop appliances, such as waffle makers, toasters, blenders, mixers, food processors, coffee makers, and the like.

[0065] The appliance 12 can be configured to perform a cycle of operation to complete a physical domestic operation on an article. Examples of the physical domestic operations include a food preparation operation, a food preservation operation, a fluid treatment operation, a cleaning operation, a personal care operation, a fabric treatment operation, an air treatment operation, and a hard surface treatment operation. The air treatment operation can comprise, for example, air purification, air humidification, air dehumidification, air heating, and air cooling. The food preparation operation can comprise, for example, food cleaning, food chopping, food mixing, food heating, food peeling, and food cooling. The food preservation operation can comprise, for example, food cleaning, food freezing, and food storage in a specialized atmosphere. The fluid treatment operation can comprise, for example, fluid heating, fluid boiling, fluid cooling, fluid freezing, fluid mixing, fluid dispensing, fluid filtering, and fluid separation. The cleaning operation can comprise, for example, dishwashing, fabric washing, fabric treatment, fabric drying, hard surface cleaning, hard surface treatment, hard surface drying, carpet cleaning, carpet treatment, and carpet drying. The personal care operation can comprise, for example, hair treatment, nail treatment, body massaging, teeth cleaning, body cleaning, and shaving.

[0066] The components associated with the appliance 12 can include any devices, parts, software, and the like that participate in the operation of the appliance 12, either directly or indirectly. Some of the components have a corresponding controller (main controller, motor controller, user interface, etc.), which can be a simple microprocessor mounted on a printed circuit board (a control board), while other components have no controller. The components can comprise one or more devices that are controlled by the controller. Typically, the controller components in cooperation, either directly or indirectly, through other components, control the operation of all of the components and the associated devices to implement a cycle of operation for the appliance 12.

[0067] One or more components affected/effecting the toolkit 10 can comprise another appliance 12, one or more components on the appliance 12 or in another appliance 12, or an accessory device or component thereof for use with the appliance 12. For purposes of describing the invention, it will be understood that when reference is made herein to the use of the toolkit 10 in conjunction with the appliance 12, the same applies to the use of the toolkit 10 in conjunction with another appliance 12, with one or more components of the appliance 12 of another appliance 12, and with an accessory device or component(s) thereof for use with the appliance 12.

[0068] The appliance 12 can be communicatively coupled to the toolkit 10 via a communications network 18 existing at least partially within the appliance 12 and/or at least partially external to the appliance 12 as appropriate. The communications network 18 comprises all of the coupling elements communicatively linking the various parts of the toolkit 10 and the appliance 12, as well as any coupling elements communicatively linking additional devices or resources to the toolkit 10 and/or the appliance 12 (e.g. a coupling element connecting the appliance 12 with an accessory). For example, the communications network 18 can comprise an internal communications network of the appliance 12 enabling communication between the various components within the appliance 12, an external communications network connected to the toolkit 10, and a coupler for communicatively coupling the two networks. The coupler can comprise a communication driver configured to establish a communications link between the toolkit 10 and the appliance 12. Looking also at FIG. 2, the communication driver can be a smart driver 54 having expanded functionality enabling the smart driver 54 to create, modify, and/or interpret content 20. The communications network 18 can further comprise an additional communications connection between the appliance 12 and/or the toolkit 10 and one or more additional devices, such as the accessory, an external network, a second appliance 12 or accessory, or one or more components thereof. As a non-limiting example, the additional communications connection can be to the Internet. The communications network 18 can comprise, at least in part, a smart coupler 56 as is disclosed in International Patent Application Publication No. 2009/058770, which is incorporated by reference herein in its entirety. The smart coupler 56 can incorporate the communications driver, which can be the smart driver 54.

[0069] The toolkit 10 enables a user 14 to create content 20 that can be provided to or otherwise obtained by one or more content targets 22 to affect the functionalities of the appliance 12. Content 20 can be formatted as at least one of a relational database, XML document, CSV file, binary file, data collection, memory structure, object structure, object graph, object tree, memory heap, machine code, source code, and text file, images, text, data elements, or other type of information associated with the toolkit 10 that can be interpreted, converted, propagated, created, modified, or otherwise used for some purpose by the toolkit 10, the appliance 12, or an associated device or component. Examples of content 20 include but are not limited to a cycle structure, a custom cycle, a branded cycle, user-attached data about appliance control functionality, a fault tree, a diagnostic test, an appliance user interface 64 (see FIG. 6A for example), appliance network communication, routing tables for appliance network communication, stain treatment, cooking, cooking algorithms, cooking vessels, meal preparation, dish preparation, recipes, unit conversion, ingredients, ingredient substitution, dietary needs, appliance use and care, appliance FAQ, consumables meta data, and information associated with consumable, a cycle definition, cycle structure information, a paired element, source identification information, a message data payload structure, an electronic document that is human-readable, machine-readable, a communications specification/protocol, and information about a consumable.

[0070] Content 20 can comprise various forms of data or data elements, including appliance user domain data 180 (see FIG. 24), control system domain data 182 (see FIG. 24), and source identification domain data 186 (see FIG. 46). Appliance user domain data 180 includes information related to a user's 14 use of an appliance 12. It includes such things as washing and cooking preferences, recipes, user demographics, choices and selections that user makes, and the like. Control system domain data 182 includes information related to the control and operation of an appliance. It includes such things as cycle structures, cycle definitions, message pay-
loads, communication protocols, and the like. Source identification domain data 186 includes information related to the sources of goods and services and includes things such as trademarks, brand names, service marks, jingles, and the like. User interface domain data includes information related to interacting with a user interface 64, which is preferably a graphical user interface 68. It includes such things as widgets, animation definitions, buttons, bars, sliders, knobs, and the like, whether real or virtual.

[0071] A content target 22 comprises any entity that receives content 20. Non-limiting examples of different content targets 22 include the toolkit 10, the appliance 12, the communications network 18, a system configurator 28, editors 30 and 32, converters 34, viewers 38, an appliance control system 90, a user interface 64 and graphical user interface 68, a web browser or web page, a personal computer 70, an application 50, a computer program, a handheld device, a remote client 72 such as a cell phone, a printer, and any hardware or software components or devices associated therewith or included therein.

[0072] As shown in FIGS. 2-4, the toolkit 10 comprises system configurator 28 having a model editor 30, a model instance editor 32, and one or more converters 34 configured to enable a user 14 to create, modify, and/or propagate content 20, such as models 40, model instances 42, and model instance variants 44, respectively. The toolkit 10 can further comprise one or more viewers 38 that function as content targets 22 and provide a visual display corresponding to the received content 20. Depending on the particular type of viewer 38 being used, viewers 38 can produce one or more of a variety of different displays or views ranging from schematic diagrams to code to images. The communications network 18 is configured to establish a communicative link between the system configurator 28 and at least one component associated with the appliance 12.

[0073] Different content targets 22 can use the same content 20 for different purposes. For example, a model instance editor 32 that receives content 20 in the form of a model instance 42 can provide a visual diagram of the model instance 42 and enable the user 14 to edit the model instance 42. However, if the same model instance 42 is sent to the appliance 12, the appliance 12 can be enabled with new operational capabilities, such as new cycles of operation. In another example shown in FIGS. 5 and 6A, the appliance 12 can receive the model instance 42 from the model instance editor 32 and provide the model instance 42 to a graphical user interface 68 of the appliance 12 in order to cause the graphical user interface 68 to display certain images and text.

[0074] Converters 34 can enable the flexible usage of content 20 by converting data elements or content 20 created by one of the editors 30, 32 into content 20 of a form suitable for use by a particular content target 22. For example, a type of converter 34 called a model instance converter is configured to produce a model instance variant 44 based on a model instance 42. Another type of converter 34 called a simple converter can simply propagate data elements or a file stored in memory and comprising data elements created by the toolkit 10 without having to substantially convert the data elements. Simple converters are best used when the content target 22 can operate directly on the data elements created by editors 30, 32, such as a content target 22 in the form of a viewer 38 included in the system configurator 28. Converters 34 are typically used to enable the transfer of data elements amongst the various entities of the toolkit 10 and appliance 12. A converter 34 can potentially also act as an exporter, which functions similarly to the propagating function described previously. The toolkit 10 can also include a converter 34 in the form of an encoder to encode content 20 onto a consumable information holder or other component.

[0075] The system configurator 28 can optionally further comprise one or more applications 50, which can also include one or more viewers 38 and can use content 20 provided by the system configurator 28. One or more applications 50 can also be communicatively coupled to but not included within the system configurator 28. Content 20 provided by the system configurator 28 can optionally be supplemented by content 20 provided by or created using resources 46, which can include any entities capable of producing content 20 or being used by another entity to generate content 20.

[0076] For testing, diagnostic, and engineering purposes, a link can be established between the system configurator 28 and a content target simulator 52 (FIG. 2). The content target simulator 52 typically comprises software and is intended to provide a realistic simulation of the operation of the appliance 12. The toolkit 10 thus comprises software configured to enable a user 14 to effectively command operation of the appliance 12 or of an appliance simulator and to create data or data elements for display to a user 14 as content 20 in a viewer 38 of the toolkit 10 based on the operation of the appliance 12. The user 14 can observe the content 20 in the viewer 38 and create or modify the content 20 using the toolkit 10 in response to communication over the communications network 18 and link.

[0077] A model 40 is a very robust, thorough, and thoroughly-vetted collection of data elements or structures equivalent to a UML class diagram. A model 40 consists of a plurality of class definitions where each class has a plurality of properties and each class can reference other classes a minimum and maximum number of times, which may be infinite. Classes can reference other classes via a named property. Classes can also, in effect, serve as extensions of other classes in order to inherit their functionalities, property definitions, and references. Classes can implement interfaces, which are definitions of collections of functions each having a set of arguments, wherein each argument can be set to one of a set of valid values. The purpose of the class definition is to provide rules or constraints for creating model instances 42 and model instance variants 44, which are, in essence, runtime instances of the model 40. Thus, the toolkit 10, in effect, enables users 14 to create runtime instances of a class diagram and is configured to create, manage, and/or edit models 40, model instances 42, and model instance variants 44, as well as data elements or information associated therewith, that are configured to effect the functionality of one or more components associated with the appliance 12.

[0078] As described in more detail hereinafter with respect to FIGS. 25 and 26, the model editor 40 is typically used by a user 14 associated with the manufacturer 14A of the toolkit 10 or of the appliance 12, such as an engineer or software developer, to refine and constrain models 40 prior to the models 40 being made available to users 14 external to the manufacturer 14A. The provides the manufacturer 14A with the ability to control the specific toolkit 10 functionalities available to users 14 outside the company, and, in doing so, provides the ability for the manufacturer 14A to offer and sell licenses for the toolkit 10 that enables users 14 access to only certain levels of functionality. Each particular model 40 in essence is a template or a plurality of constraints defining at least part of
the functionality of the system configurator 28. Each model 40 enables at least one model instance editor 42 and defines the functionalities of the model instance editor 42. Thus, n models 40 can be used with the toolkit 10 to generate n instances of data elements derived therefrom. An exemplary data element can comprise at least one representation of a portion of a message data payload to be sent across the communications network 18.

[0079] The model instance editor 42 creates instances of data elements that comprise a model instance 42 and that are related to appliance 12 functionality and derived from the appliance user domain data 180 model. The model instance editor 42 is configured at least in part by the appliance user domain data 180 model irrespective of the appliance 12 so that the toolkit 10 can be used with different appliances 12. Validation rules, which essentially comprise a communications protocol, for the content 20 can be derived from the appliance user domain model. The model instance 42 can comprise a hierarchical data structure, a graph, a fault tree, or a relational database and can be configured or developed by a user 14 interacting with the user interface 64.

[0080] Referring now to FIGS. 5-7, models 40 can be grouped into a variety of types based on the function of the model 40 and model instances 42 created therefrom. A user interface domain data model 40A can be used to create user interface data domain model instances 42A, such as that illustrated in FIGS. 5 and 7, which are used to control the functionality of a user interface 64 of the appliance 12, which can be a graphical user interface 68. In this example, the user interface domain data model instance 42A includes user interface control objects 60A-C displayed in the model instance editor 32 and corresponding to each of the three user interface controls 62A-C displayed on the user interface 64 of the appliance 12. The user interface control objects 60A-C are converted or propagated by a converter 34 included in the system configurator 28 into content 20, which is sent to a content target 22 of the system configurator 28, the viewer 38. Looking now to FIG. 6A, the viewer 38 then creates a rendering of the graphical user interface 68 as it would appear on the appliance 12 once the user interface domain model instance 42A has been sent to the appliance 12 as content 20. This simulation enables the user 14 to observe and, if desired, modify the appearance of the graphical user interface 68 without having to repeatedly reprogram the appliance 12 itself. As illustrated in FIGS. 6B and 6C, the user interface domain data model instance 42A can also be sent to other content targets 22, such as a personal computer 70 or a remote client 72, as content 20 to enable the user 14 to visualize the user interface 64 and tailor the user interface 64 to his or her particular needs and tastes.

[0081] A sequence model 40B as shown in FIG. 7 is another type of model 40 that can be used to create cycles, fault trees, recipes, and tests (see also FIG. 47). As described herein, the same sequence model 40B can be used to generate a variety of different types of sequence model instances (e.g. instances for a cycle, a fault tree, a recipe, or a test). In some alternative embodiments, multiple sequence models can be required to generate the different types of sequence model instances. A sequence model instance for a cycle 42B that is derived from the sequence model 40B is illustrated as a content target 22 of the user interface domain data model instance 42A. In this example, an object 60A of the sequence model instance for a cycle 42B corresponding to a user interface control 62A for dispensing ice is propagated or, if necessary, converted by a converter 34 associated with the user interface domain data model instance 42A or sequence model instance for a cycle 42B into the appropriate format and is provided to the sequence model instance for a cycle 42B.

[0082] Due to this binding of user interface domain data of the user interface domain data model instance 42A and control system domain data 182 of the sequence model instance for a cycle 42B, when a user 14 actuates the user interface control 62A, the transition will be initiated, and the cycle specified by the sequence model instance for a cycle 42B and created in the manner explained below will be carried out to produce ice.

[0083] Objects can be composed of a plurality of other objects according to the objects field definitions. If an object comprises a method which has executable software to set the value of a field defined to hold an object, then that object can be reconfigured by changing the value of the field from a first object to a second object. This reconfiguration can then result in a different composite or overall appliance control system 90 behavior. There are many useful purposes for an appliance control system 90 whose behavior can be changed by changing the values in a first objects field to a third object from a second object. For example, a cycle accessory could use this technique to change a cycle structure 80. Likewise, both a consumables reader and a recipe book wand could use these techniques to customize the behavior of the appliance control system 90 according to appliance user domain data 180, source identification domain data 186, user interface domain data the data about the cycle, data about a consumable, and the like.

[0084] There are many mechanisms which can initiate and manage the dynamic configuration of an appliance control system 90. However, these mechanisms (see FIG. 34) will need a common design framework with which to accomplish the dynamic configuration. Some portions of the dynamic configuration can be accomplished during the compile process, while other portions may be accomplished at post-compile time (also known as runtime).

[0085] FIG. 7 illustrates several ways that the appliance 12 can obtain information necessary to carry out appliance 12 operation, including information about cycles of operation, and generate a cycle structure to perform a cycle of operation. Here, cycle structure information 82 represents information about or associated with a cycle structure 80 to be produced by the cycle engine 88. Cycle structure information 82 can include modifications to be made to an existing cycle structure 80, information to be used to create a new cycle structure 80, or a cycle structure requiring conversion or some sort of manipulation into a cycle structure 80 suitable for use with the particular appliance 12. Cycle structure 80 represents a set of instructions for use by the appliance control system 90 of the appliance 12 for carrying out a cycle of operation. An exemplary appliance control system 90 is illustrated in FIG. 9 and is described in detail by International Patent Application Publication No. 2006/135758, which is incorporated by reference herein in its entirety. In one embodiment, the cycle structure 80 can be created by using messaging for communicating the cycle structure information 82 to the cycle architecture 86 via the communications network 18, at which point the cycle engine 88 can discover information for creating or modifying cycle structure 80 for use by the appliance control system 90. The cycle engine 88 then proceeds to build a new or modified functional cycle structure 80. Optionally all messages can be routed through an embedded virtual router (EVR) 92, which
results in the cycle engine 88 using its own configuration API for building the new or modified cycle structure 80. The execution by the cycle engine 88 to create or modify the cycle structure 80 can also be accomplished through the EVR 92.

An arbitrary software component 94 in communication with the cycle engine 88 or in communication with the cycle architecture 86 can also be used to create a new or modified cycle structure 80. The arbitrary software component 94 can reside in a variety of locations with respect to a controller component comprising the cycle architecture 86. Hence, all messages between the arbitrary software component 94 and the cycle architecture 86 can be optionally routed through an EVR 92 across the communications network 18.

As well, the cycle architecture 86 can optionally communicate with the appliance control system 90 through an EVR 92.

In another scenario, an operational cycle accessory, such as the toolkit 10, can be communicatively coupled to the communications network 18, discover the cycle architecture 86, and send the cycle architecture 86 messages to affect its structure and, ultimately, its execution. In this case, the operational cycle accessory would typically include a combination of software and data to accomplish the configuration of the cycle architecture 86. Alternatively, the aforementioned cycle architecture might send a discovery message seeking identification of all sources of the cycle structure 80. Sources of the cycle structure may be in ROM, Flash, EE Prom, an operational cycle component, and/or an external source connected to the communications network 18. Once the cycle structure information 82 located and retrieved, the cycle engine 88 can commence modifying its own cycle structures 80 according to the new cycle structure data. As shown in FIG. 7, when the converters 34 associated with the cycle structure information 82 and the cycle structure 80, read the sequence model instance for a cycle 4213, the converter 34 associated with the cycle structure information converts the sequence model instance for a cycle 4213 into cycle structure information 82, and the converter 34 associated with the cycle structure converts the sequence model instance for a cycle 4213 directly into a cycle structure 80. Both the cycle structure information 82 and the cycle structure 80 generated by the associated converters 34 are generated based on the same content 20 comprising the sequence model instance for a cycle 4213.

In another embodiment of a cycle architecture 86, a first portion of the cycle structure information 82 is compiled and a second portion is made available at runtime. The second portion can include a plurality of cycle structure data, either in direct or indirect form, which can be combined with the first portion such that the cycle engine 88 operates on the aggregate of the first and second portions to create operational cycle execution software. The second portion can represent differences in the first portion where differences may be additions, deletions, or modifications to elements, their relative orders, or their relative relationships within the cycle structure 80. The cycle engine 88 can appropriately apply the differences represented in the second portion by looking at the identifiers of the elements of the first portion of the cycle structure information 82 and the identifiers of the elements of the second portion of the cycle structure information 82. The advantage of this embodiment of a cycle architecture 86 is that changes to the aggregate cycle structure 80 can be made while preserving the first portion such that subsequent corruption or absence of the second portion would not effect the integrity of the first portion, thus enabling the operation cycle execution software to revert to compiled default state, such as might be supplied at the factory. A second advantage of this embodiment is that specialized variants of the first portion can be designed which can accommodate the constraints presented by the appliance control system 90 and more specifically the controlling components of the appliance 12 such as limited memory and also provide capability for receiving and adapting to a second portion, providing flexibility and configurability within the constraints for the cost of the specialized variants. For appliances 12, this can be an important requirement in some cases.

Alternatively, when an operation cycle accessory is disconnected from the cycle engine 88, the data of the second portion can be optionally removed by the cycle engine 88, causing a reversion to the factory default state. This is a form of anti-piracy protection in that the operation cycle accessory must be present for the additional functionality represented by the accessory to be available to the appliance 12. Optionally, the connection between the appliance 12 and the operation cycle accessory can include a transfer of the first portion into a memory in the appliance 12. In this case, additional operation cycles can be retained without the permanent presence of the operational cycle accessory. It should also be noted that an operation cycle accessory can be virtual in that the software and data and ability to communicate with the cycle engine 88 can reside on an external device connected to the cycle engine 88 via communications network 18, and not physically attached to the containing appliance 12.

It is to be noted that an operational cycle component can have other elements that are not the aforementioned operation cycles or constituent data and compiled portions. For example, the operational cycle component can include software code to configure a cycle engine 88 for communication and other functions or code to put software architecture into an alternate mode for the purpose of diagnostics or changing memory.

An appliance cycle of operation performed by the appliance control system 90 can be optimized by information associated with consumables on which the appliance is operating. For example, the cycle structure 80 could be built specifically to accommodate some properties or attributes of the consumable or to accommodate some properties or attributes of a consumable holder. The body or bodies that comprise information, identifiers of functionalities, properties, attributes, and property and attribute values related to consumables can be referred to as sources of information about a consumable or “consumable information holders.” Examples of consumable information holders include the consumable itself, a datu pod, the consumable holder, a user interface, and a tag. The consumable holder can be a sensing consumable holder that might use a lid sensor, for example, for sensing attributes about the consumable contained therein. These attributes could then be used by the appliance 12 to further refine operation of the consumable holder. For example, if a particular consumable holder is supposed to dispense 2 ounces, a lid with an amount sensor could be configured with an analog circuit coupled to the appliance 12 to provide a level or volume feedback so that the appliance 12 can dispense exactly 2 ounces rather than a time-based approximation.

Information associated with a consumable can include amount and/or composition or other attributes that would characterize the magnitude of the usefulness of the consumable. In this case, the cycle architecture 86 may adapt itself based on the information. For example, if the consum-
able were a dishwashing rinse aid and the consumable holder had only 90% of the standard dose, the cycle architecture might adapt itself to this condition by increasing the time of the rinse phase to compensate for the lack of rinse aid. Information associated with a consumable can also include parameters of an operating cycle such as personal preferences of a user (e.g., doneness or crispiness preferences), and data about the consumable holder, the appliance, or other accessories or components thereof.

[0093] In a laundry example, the appliance control system may provide information to the cycle architecture about process variables like soil level, load size, soil type, etc. Based on this information associated with a consumable, including the process variable information, the cycle architecture or an arbitrary software component can reconfigure the cycle structure to adapt to the process variable information. The consumable holder may comprise the arbitrary software component and be able to reconfigure the cycle structure to adapt to the process variable information. Reconfiguration can be accomplished in at least two ways. In one way, the arbitrary software component can read the cycle structure and communicate with the cycle engine. In a second way, an arbitrary software component can be preconfigured and communicate that configuration to or instruct the cycle engine about the configuration.

[0094] One example of commands associated with an operating cycle is a collection of key value pairs. Keys comprise parameter names having a meaning, wherein the meaning is known by the cycle engine such that values associated with the keys are thereby associated with the meanings. This enables the values to be used in the contexts of the meanings to modify and/or control the cycle of operation of the appliance.

[0095] Another example of commands associated with an operating cycle is a byte array representing a message packet for a network. In one embodiment of this example, the byte array could be arranged according to the packet definition disclosed in WO2006135726 comprising a functional identifier, an op code, and a message data payload, wherein the identifier and op code relate to an executable function or method implemented by the engine and cycle engine API. Further, the arguments or parameters of the function or method information to the data elements contained in the payload of the message packet.

[0096] The consumable holder, therefore, can contain all the functionality of and participate in all the embodiments that an operational cycle accessory in communication with an appliance having a cycle architecture can. Therefore in one embodiment, a consumable holder is an operation cycle accessory that further physically contains and can also further be enabled to directly actuate the introduction of a consumable into an appliance.

[0097] As seen in FIG. 8, content can be derived from or provided by components or resources outside the appliance (external content) or from memory or other information contained within the appliance (internal content) and acquired by a content acquisitioner. The appliance software framework, which includes the cycle architecture, receives the content and creates an appliance control functionality. The appliance control functionality provides and controls the user interface and user interaction, as well as provides and controls the appliance control system. As an example, FIG. 9 also illustrates the appliance control system disclosed in International Patent Application Publication No. 2006/135758 and further includes the system configurator for managing the functionality thereof.

[0098] As shown in FIGS. 10-15, sequence model can also be used to generate a sequence model instance for a fault tree. Appliances are often diagnosed and serviced using an appliance fault tree in which the sequence model instance for a fault tree serves to present a user with various displays or views on the user interface informing the user of possible problems and solutions associated with the appliance. The initial step of an appliance fault tree will normally be associated with a symptom of failure or state of the appliance.

[0099] With continued reference to FIGS. 10-15, the exemplary initial step is performed upon determination of a state of the appliance in which the user is experiencing slow or no water dispensing. Each step of the appliance fault tree including the initial step can have one or more actions. Actions can be various tasks or checks performed at each step. Exemplary actions can comprise, but are not limited to, taking a measurement, asking a question, requesting user input, describing an observation, and the like. The exemplary action associated with the initial step is to ask a question, “Is the refrigerator connected to a water supply?”. The action can also comprise obtaining the answer, which can be “Yes” or “No.”

[0100] Transitions are paths to other steps in the fault tree and that are normally conditional on the result of a given step or action. At each step of the sequence model instance for a fault tree, an action can be performed comprising asking a question regarding operation of the appliance, and the question can be presented on the user interface. Once an answer to the question has been obtained, the sequence model instance for a fault tree will perform a transition to another step in the appliance fault tree. As shown in FIG. 11A, each question will also have corresponding content that is displayed on the user interface. Typically, question-based content will include buttons or other user interface controls that will enable the user to input an answer to the question. Alternatively, the appliance can automatically determine the answer to the question using various components, such as sensors. Thus, an answer can be obtained via user interaction with the appliance via the user interface controls, or automatically by the components of the appliance or associated device.

[0101] As shown in FIG. 10, when an answer of “Yes” is obtained when the initial step is carried out, the appliance fault tree can transition to the next step. Thus, the question and answer function as arguments that, in combination, form a conditional statement in the appliance fault tree. While proceeding through the appliance fault tree, the specific steps, actions, and transitions are performed based on whether the various conditional statements in the appliance fault tree are true or false. If a conditional statement is false, no transition will occur, and the appliance fault tree will proceed in order. If a conditional statement is true, then a transition can be performed, which can act as a path to a particular step, action, and/or transition. In some cases, the action can be displaying a solution on the user interface.

[0102] As shown in FIG. 10A, an answer determination attribute editor, which is also a component of the model instance editor, can be used to edit the content displayed...
to the user 14 at a given transition corresponding to a given question and answer conditional statement. The answer determination attribute editor 120 is illustrated as having a number of well-known elements frequently included in computer-based editing applications, such as clickable buttons 122, a display window or viewer 38, and a text entry box 124.

[0103] As shown in FIGS. 12-15, the sequence model instance for a fault tree 42C can also be used to present a use and care guide 130 to the user 14 via the user interface 64 of the appliance 12, which can comprise the GUI 68. Content 20 comprising text to be displayed to the user 14 can be created using a document model instance 42G (FIG. 43) for a use and care guide 130, which specifies content 20 can be displayed on the user interface 64 that enables a user 14 to select a symptom 132 included in the use and care guide 130. The selection of a symptom 132 can automatically bias the user 14 to an entry or starting point in the sequence model instance for a fault tree 42C so that the user 14 does not have to waste time looking through irrelevant symptoms. In addition, a given appliance 12 can have more than one fault tree 110 associated with it. For example, there can be a fault tree 110 associated with different components or different subsystems in the appliance 12. There can also be different fault trees 110 associated with accessories connected to the appliance 12, and each fault tree 110 can have an initial step A that would normally serve as the starting point for entry into the respective fault tree 110. It may be, and often is the case, that any given fault tree 110 for an appliance 12 might have multiple entry points. Further, a transition, as discussed previously with respect to FIGS. 10-15, is not limited to transitioning to a sequential step within the same fault tree 110. For example, a transition from a first step on a fault tree 110 can lead to a second step on another fault tree 110.

[0104] The fault tree 110 and/or use and care guide 130 provided by the sequence model instance for a fault tree 42C can also be presented in a viewer 38 as content 20 in the form of a diagram 140 as shown in FIGS. 14 and 15. The user 14 can troubleshoot problems by simply using a content target 22 capable of presenting the content 20. For example, as shown, a user 14 can use the personal computer 70 to view a web page including the information, or the user can use a printer 142 to print out a copy of the diagram 140. In either instance, the sequence model instance for a fault tree 42C can be used to diagnose problems and potentially find a solution without requiring a visit from a serviceperson.

[0105] Looking now to FIGS. 16-23, a message data payload model instance 42D is used to manage message data payloads 150 comprising a first portion 152 having usable data and a second portion 154 having information to describe the usable data. The first and second portions 152, 154 can comprise an ordered collection of message elements 156 or at least one message element 156. One of the first and second portions 152, 154 can have a direct or indirect reference to the other of the first and second portions 152, 154, which can effectively bind the portions. The constraints defined by the model 40 can be used within the model instance editor 32 to create the association between the first and second portions 152, 154. Various message elements 156 can be compiled to create a portion 152, 154 using the model instance editor 32 during creation of the message data payload 150 and can comprise meaningful text describing the meaning of the message element 156. Usable data from the communications network 18 can be combined with non-usable data describing the usable data wherein the user 14 can understand the meaning of the usable data. Based on the message data payload model instance 42D and the properties 158 thereof, a viewer 38 can display a complete specification 160 that updates in real time as the user 14 edits the message data payload model instance 42D and properties thereof.

[0106] Specifically, FIGS. 16-18 show the creation and advantages of useable data in the inventive appliance development toolkit 10. The system configurator 28 displays the message data model instance 42D in the model instance editor 32, a viewer 38 showing properties 158, and a viewer 38 showing the specification 160. Elements and choices of a command structure or sequence are created in the model instance editor 32 as an instance of a message data payload 150. A first portion 152 of a message element 156 comprises useable data and is set in byte 1. A second portion 154 identifies the first portion 152 and is set in thus example in byte 0. The model instance editor 32 can have constraints that limit or guide what a use can do in creating message payloads 150. In any event, the model instance editor 32 creates an association between the first and second portions 152, 154 where rules for data representation provided by the communications network 18 over which the message payload 150 is to be sent provide the constraints.

[0107] A user interface 64 or viewer 3 can display a visualization of the message data payload 150 from the model instance editor 32 so that a user 14 can conveniently create the message data payload 150 for immediate use and see a graphical representation of the message data payload 150 as it is created. An example of that display is seen in FIGS. 17 and 18. In FIG. 17, a viewer associated with an application 50 can display relevant data including the identifiers (second portion). As shown in FIG. 18, a specialized viewer 38 associated with an application 50 or, alternatively, incorporated directly into the system configurator 28 can also be associated with a command generator 170 such that the associated viewer 38 displays the various message elements 156 of the message data payload 150 and the command generator 170 enables the user 14 to define and initiate the sending of a message data payload 150 to affect the operation of the appliance 12. The command generator 17 can include one or more buttons 122 for initiating the sending of a defined message data payload 150.

[0108] FIGS. 19-23 show in steps the creation of a message data payload model instance 42D using variables, values, and value holders, which will be described in more detail hereinafter in FIG. 37. See the description of holders, infra. As well, FIG. 20 shows the use of menus 174 and forms 176 for guiding or limiting a user 14 in selecting and inputting information according to the constraints. An error message 172 can be displayed if a property 158 or parameter associated therewith is incorrect or improper according to the constraints. A model instance editor 32, which includes constraints as will be discussed in more detail hereinafter, is constrained by a model 40. In FIG. 20, an API object has been selected and the user 14 has right clicked the object, bringing up menu 174 having an “Insert New” feature. Referring to a message data payload model 40C of FIG. 37, an API is allowed to have a minimum of zero relationships with a message data payload 150 and a maximum of n or infinite relationships with a message data payload 150. Therefore, if the user selects the “Insert New” item on the menu 174, a sub-menu (not shown) or form 176 can appear, enabling the user 14 to choose to create a message data payload object. In this case, the model instance editor 32 reads the model 40
such that it is informed by the model 40 what the possible relationships between each current and potential objects are so that the model instance editor 32 editor can configure its functionality from the information in the model 40 so as to constrain itself according to the model 40. In this way, a constrained appliance development toolkit 10 constrained by a model 40 can limit the types of objects created and the available relationships between objects which in turn limits the ability to create content 20, which in turn limits the appliance control functionality.

[0109] FIG. 24 illustrates types of model instances 42 that can be associated or bound by the model instance editor 32 of the appliance development toolkit 10. Essentially anything in the different domains of data can be bound for later use. Although appliance user domain data 180 and control system domain data 182 are here shown, it will be understood that binding among other domains is equally within the scope of the invention, e.g., user interface domain data 184 and/or source identification domain 186 data.

[0110] FIG. 25 illustrates the benefit of constraining the development toolkit 10 for use by users who want to create content 20 for effecting the cycle of operation of the user interaction of an appliance 12 but do not have all the engineering skills or knowledge to do so. The constrained development toolkit 10 enables a user 14 that has less than all the required knowledge or skills to create content 20 that effects the cycle of operation or the user interaction of an appliance 12 wherein the effect is less than the full effect that content 20 from an unconstrained appliance development toolkit 10 can create. The constraints used to constrain use of the toolkit 10 can be specified within a model 40. It is to be understood that for the purposes of describing the invention, unless otherwise specified, reference to the toolkit 10 herein can be understood as a reference to a constrained toolkit and/or an unconstrained toolkit.

[0111] Appliance manufacturers build appliances for a competitive market and compete with one another in the areas of cost and innovation. Accordingly, manufacturers 14A must continuously invest in new products, new technologies, and new innovations while simultaneously reducing cost and improving quality. The ability of an appliance manufacturer 14A to develop a means by which to engage thousands of additional persons for the purpose of creating new product innovation without raising costs would be a disruptive competitive advantage for that manufacturer 14A. However, because only highly trained and specialized engineers can successfully and properly create appliance control functionality, previous attempts by manufacturers 14A to engage the thousands of additional persons in an uncontrolled manner have not resulted in the production of functional and properly-engineered appliance control functionality. As appliance control functionality plays a critical role in a person’s everyday life, such as by affecting the clothes people wear, the food they eat, and the air they breathe, proper implementation of appliance control functionality is a necessity. Many appliance control functionalities are also potentially dangerous and must be precisely managed by the specialized and intricately engineered appliance control system, such as appliance control functionalities associated with high voltage sources, high heat sources, gases, liquids, and chemicals.

[0112] The use of constraints to contain the appliance development toolkit 10 enables the thousands of additional persons to create content 20 that effects and/or the cycle of operation or the user interaction of an appliance by providing guidelines and rules for innovation. In particular, the constraints can enable users 14 to create content 20 that effects/ affects only certain appliance control functionalities deemed appropriate for manipulation by the manufacturer 14A while preventing users 14 from creating content 20 that effects/ affects the appliance control functionalities associated with critical systems and components of the appliance 12. This enables the manufacturer 14A to ensure that the appliance 12 is safe for use by maintaining the integrity of the core appliance control functionalities. For example, the manufacturer 14A would constrain the toolkit 10 so as to prevent users 14 from manipulating precision controls, such as those for high heat, electricity, or harmful substances, so that the food, clothing, air, or other article or elements is properly operated upon by the appliance 12.

[0113] As shown in FIG. 26, there are three approaches to providing a constrained appliance development toolkit 10. They are through a constraining model 40, a constraining model instance 42, and hard-coded constraints, which can comprise content 20 as previously described. Constraints define at least a portion of the functionality of the constrained appliance development toolkit 10. It is generally the model instance editor 32 of the system configurator 28 which uses the constraints to partially limit and partially control the functionality and therefore the content 20 which the system configurator 28 is able to create.

[0114] As shown in FIG. 28 and in FIGS. 7 and 8, appliance control functionality can be created from content 20 generated from an appliance development toolkit 10. This is also shown in FIG. 25 via first content 20 and second content 20 created by the appliance manufacturer 14A and a user 14 respectively.

[0115] Referring back to FIG. 25, the appliance manufacturer 14A may provide a constrained development toolkit 10 which is hard-coded. The appliance manufacturer 14A can also use an unconstrained toolkit 10 to create the third content 20, which can include a constraining model 40, a constraining model instance 42, or both. In the latter two cases, the constrained appliance development toolkit 10 uses the third content 20 to define at least a portion of the constraints.

[0116] Referring back to FIG. 26, it is generally the model instance editor 32 of the system configurator 28 which uses the constraints to partially limit and partially control the functionality and therefore the content 20 which the system configurator 28 is able to create. The message data payload 150 instance may have been created by an unconstrained model instance editor 32 or by a constrained model instance editor 32. The system configurator 28 of the appliance development toolkit 10 (unconstrained and constrained) is able to load multiple model instance 42 files in model instance editors 32 for the creation of and associations between objects.

[0117] A constrained model instance editor 32 constrained by hard-code is shown in FIG. 26. This approach can achieve the same results as the other two approaches, but at a higher development cost over time because each new model 40 or each new model instance 42 interaction needs to be hard-coded. The previous two approaches rely on a data driven approach with a lower cost over time.

[0118] FIG. 27 includes an illustration of using a constraining model instance 42. On the right side of the model instance editor is a sequence model instance for a cycle 42B for a washing machine. The model instance editor 32 is being used to create a custom cycle with the sequence model instance for a cycle. As shown, the custom cycle includes a transition from
the idle state to the fill tub state wherein the action object for the fill tub state is responsible for the exact control actions to be taken when the fill tub state is entered. In an unconstrained toolkit 10, the user 14 can specify any control action from the universe of control actions as the action to be taken in the fill tub state. However, the constrained toolkit 10 includes a message data payload model instance 42D which provides a set of control actions less than the universe of control actions such that the user can associate at least one command from the message data payload model instance 42D with the fill tub action object of the sequence model instance for a cycle 42B in order to define the control action to be taken when the fill tub state is entered. Note that the level limit on the fill level message element 156 is between 20 and 80%. This prevents the user 14 from specifying a value for fill level either above 80% or below 20%.

[0119] FIG. 28 depicts the appliance development toolkit 10 interacting with an appliance 12 via its appliance software framework 104 by way of content 20 created by the toolkit. In this embodiment, the content 20 is created by one or more model instance converters 34 and includes a builder file 190 and a plurality of resources 192, which can comprise one or more resources 46. A resource 192 can be a data set containing data. A resource 192 can be a file or collection thereof; a database, a stream of streaming data, an event source, a network connection for communicating data and the like. In all cases, the nature of the data for a resource 192 ranges from images and videos to XML, relational databases, language conversions, and animation definitions.

[0120] Consumers/users 14 enjoy dynamic user interfaces 64, especially graphical user interfaces 68. Even better are multi-media interfaces that combine audio, visual, and tactile stimuli to create the ultimate user experience. However, users 14 keep their appliances for 10-12 years, and as such it is desirable to provide a variety of user experiences over time to keep the user 14 engaged and excited about the user experience of the appliance 12. The capability to update and transform a multi-media user interface 68 on an appliance 12 is desirable. Themes 194 are collections of resources 192 which can be applied to the components or controls of a multi-media user interface 68 through a mapping at runtime. Theming is the application of themes 194 to the multi-media user interface 64 at runtime such that the user interface 64 transforms dynamically in response to the application 50.

[0121] Similarly, the capability to create a very dynamic user experience wherein a plurality of user interface controls or stimuli cause other plurality of user interface stimuli to trigger is desirable. Moreover, an additional feature is to have the different pluralities of user interface stimuli related through a mapping so that when the mapping changes, the user experience also changes. An animation framework 196 includes animation execution software and animation definitions connected to other components of the appliance software framework 104, including properties of the UI controls 62 so that the rendering of the UI controls 62 is affected by the animation execution software operating on the animation definition.

[0122] In both cases of theming and animations 198, creating associations between resources 192, animations, themes 194, and user interface controls 62 is essential and complex. The appliance development toolkit of FIG. 28 is configured to create the necessary object representations and associations therebetween in order to generate the content 20 necessary for the appliance software framework 104 to build the objects at runtime, including UI controls 62, animation definitions (i.e. objects), data objects from resources, and objects which associate or bind the aforementioned together to achieve the dynamic graphical and multi-media user interface 68 for the appliance 12.

[0123] The main output of the toolkit 10 in this embodiment is a builder file 190. The builder file 190 contains information including object identifiers, object type (class) identifiers, and relationships between identifiers so that a builder 200 in the appliance 12 can read the file at startup or on demand and create the runtime object collections, hierarchies, graphs that control the dynamic graphical and multimedia user interface 68 for the appliance 12. The builder file 190 is generated by a model instance converter 34 that traverses the model instance objects resident in the toolkit 10 memory and exports the builder file 190 content 20 in response. The user interface domain data model instance 42A includes instances of objects from the user interface domain data model 40A, which includes class definitions for pages and user interface controls 62 and the relationship definitions therebetween.

[0124] A view or page 202 contains one or more pages, and a user interface control (UI control) 62 contains one or more UI controls 62. Pages are objects that display a plurality of user interface components and are generally designed to be navigated to and navigated from. UI controls 62 are generally reusable templates of components that must be combined with data at runtime to create a useful control. UI controls 62 are things like buttons, knobs, slider bars, select boxes, text boxes, check boxes, image frames, movie frames, input windows, and the like. UI controls 62 have a plurality of properties which are named components of the UI control 62 which either receive or emit data. It is also possible to think of a UI control property as a variable wherein the identifier of the variable would be UI control identifier, property identifier (i.e., UI control identifier, control property identifier). Examples of UI control properties are font, color, style, size, data, shrinkable, hideable, hide, and the like.

[0125] The behavior, rendering, visualization and functionally of a UI control 62 is affected by its properties. UI controls 62 can also emit data which can also be associated with a property. Examples of properties include current data, state 246, current size, current state of visibility and the like. By connecting or associating UI control properties to representations of variables known as data sources or binding objects 204 at runtime, the UI control 62 is able to be affected by other actors in the appliance software framework 104 and to be effectively rendered. Additionally, the connection to properties is able to affect other actors in the appliance software framework 104 which are connected to or are listening to property values of a UI control 62. For example, a tactile animation can be listening to a pressed property of a UI control 62 so that when the press property is true, the tactile animation executes. The aforementioned UI controls 62, their properties, representations of variables, binding and actors objects, and the relationships therebetween are created by the builder 200 in response to the builder file 190.

[0126] To accomplish both theming and animations, the appliance development toolkit 10 creates a representational hierarchy of objects which can be exported to the builder file 190 and read by the builder 200 to create the aforementioned runtime objects of the appliance software framework 104. First the toolkit 10 is configured to create objects representing runtime UI controls 62 and to associate a data source identifi-
fier 206 with certain properties of the created UI controls 62 wherein the data source identifier 206 is later associated with a resource identifier 210 to create a first binding map, binding map 1. Next, a set of resource dictionaries 212 are created each having a plurality of resource identifiers 210 and where each resource identifier 210 is associated with a file identifier 214, which can comprise an address to a resource 192. The file identifiers 214 can be in the form of a URI, URL, URN, path, and the like. Different resource dictionaries 212 can contain the same resource identifier 210 associated with a different file identifier 214, thereby creating the basis for theming.

[0127] The toolkit 10 can also be configured to enable the user 14 to associate a plurality of theme identifiers 216 each with one or more resource dictionary identifiers 218 in a second binding map, binding map 2, so that when a theme 194 is selected at runtime, data for application to a property of a UI control 62 can be acquired by finding the address of the data through the use of the information contained in binding map 2, binding map 1 and the resource dictionary 212.

[0128] Referring still to FIG. 28, at runtime, the builder 200 reads the builder file 190 and creates the UI object controls and associates them as shown in FIG. 29 with data sources 204. Binding objects/data sources 204 are created for each unique data source identifier 206 in the builder file 190 and locator objects or resource binding objects 220 are created for each unique resource identifier 210 in the builder file 190. The binding objects 204 are associated with the properties of the UI control objects according to the builder file 190 and associated with the resource binding objects 220 according to the builder file 190. The addresses of file identifiers 214 associated with the resource identifiers 210 in the resource dictionaries 212 corresponding to the currently selected theme 194 are set into the resource binding objects 220 so that the resource binding objects 220 can acquire the data from the resources 192 when requested.

[0129] Using this arrangement, a theme manager 222 applies a newly selected theme 194 by creating new resource binding objects 220 and associating them with the appropriate binding objects 204 according to the information in the builder file 190. In this manner, a user 14 of the toolkit 10 can construct multiple mappings between resource data, UI control properties, data streams, animations, and media files, such that changing a the mappings results in a dynamic transformation to the graphical or multi-media interface 68 of an appliance 12.

[0130] There can be multiple types of resource binding objects 220. An SQL binding object will know how to execute SQL against a database found at the address of its associated locator resource binding object 220. A media binding object may know how to un-marshall a binary media file of a certain type. There can also be binding objects pointing to control system domain data 182 associated with the cycle of operation enabling either the UI control objects and or the animation definitions to interact with the appliance control system 90, appliance software framework 104, and cycle of operation.

[0131] A special type of resource 192 is a language resource. By choosing a theme 194, the graphical user interface 68 can transform between a first and second language. Also because of the many to many relationships between two or more of the theme identifiers 216, resource dictionaries 212, and resources identifiers 210 are composable, a theme 194 can have resources 192 supporting a Spanish Christmas, and another theme 194 could have resources 192 supporting a Spanish victory in the soccer World Cup, wherein there can be one resource dictionary 212 for the Spanish language, one for Christmas, and one for Soccer.

[0132] Animations 198 work the same way as do other resources 192. Animations 198 can have two binding points, an input and output. The output of an animation 198 is a function of its input value determined by its binding and its f(x) function, which can be any mathematical function. The binding to an animation is depicted in FIG. 28 wherein the animation is bound to two data sources 204 in the form of resource binding objects 220, as well as to an animation binding object. In effect, the animation 198 acts like a resource 192 of FIG. 29 having its input connected to one resource binding object and its output connect to another resource binding object. When the theme manager 222 changes themed animations 198, it creates two new resource binding objects, sets an address of the new animation definitions (either input or output) into each of the new resource binding objects, and optionally loads the animation 198 into memory for execution.

[0133] Additionally, the toolkit 10 can construct resources 192 for access by the appliance software framework 104. The appliance 12 can also have an interface for receiving a new builder file 190 and/or new resources 192 and can either combine or interchange the new and the existing files so that the appliance 12 can be updated over time with new pages 202, new themes 194, new animations 198, and new resources 192.

[0134] Looking now to FIGS. 30-42, in a first embodiment, a hierarchy of objects starts with a single root object that we can call “root.” The root object has 0 to n children and the children may be of different types (i.e., type 1 and type 2). In turn, the 0 to n children may also have children. Therefore, an object A that is a child of root and has children of B and C is considered to be both a child and a parent and can be referred to either as a child or a parent depending on the context. Except for the root, all objects in a hierarchy are a child and those with children are also parents. The root is a parent unless it has no children.

[0135] The first embodiment is a simple example of an implementation of a hierarchy wherein the parent child relationships are direct relationships. In a direct parent child relationship, the parent includes an identifier identifying each of its children. Therefore, the parent cannot be decoupled from its children because it comprises the identifiers of its children.

[0136] A second embodiment exemplifies an indirect parent child relationship wherein neither the parents nor the children include identifiers of the other. Instead, a holder object contains the identifiers of both. For example, object Q is a holder and contains an identifier of object A, object B, and object C, wherein object A is of type 1, object B is of type 2 and object C is of type 3. Objects A, B, and C do not have access to the identifiers of one another. The primary responsibility of object Q is to contain identifiers for objects A, B, and C thereby establishing that there is some type of relationship between objects A, B, and C. There are a number of ways that the nature of the relationship between A, B, and C can be ascertained. In a first example, object Q has access to information defining the possible relationships between objects of type 1, 2, and 3. In this example the information would define a first relationship definition between objects of type 1 and type 2 as being a parent-child relationship wherein type 1
must be the parent and type 2 must be the child. The information would also define a second relationship definition between objects of type 1 and objects of type 3 as being a parent-child relationship wherein type 1 must be the parent and type 3 must be the child. With the information, object Q can interpret the relationship between object A, B, and C as a parent with two children wherein A is the parent of children B and C.

A third embodiment exemplifies an alternate approach for creating an indirect parent child relationship wherein neither the parents nor the children include identifiers of the other. In this embodiment, multiple holders are used to create a holder hierarchy. For example, object Q is a holder and contains an identifier for object A. Object Q also contains an identifier for a second holder object X. Object X contains an identifier for object B. Holder object Q is a parent holder with respect to holder object X because holder object Q contains the identifier to holder object X. Therefore the relationship between object A and object B can be inferred as a parent child relationship when observed from the perspective of holder object Q and holder object X because holder object Q are in a direct parent child relationship. In this case, object A and object B are in an indirect parent-child relationship.

A forking element includes a hierarchy having a first parent object with at least two children where at least one of the two children has one or more second children and where the one or more second children have one or more third children. An interpreter of the first parent, the one of the two children, the one or more second children, and the one or more third children interprets the two children as valid values of the parent and interprets that the one or more second children is applicable to the hierarchy when the first parent is paired with at least one of the two children that is the parent of the one or more second children.

FIG. 37 shows a plurality of models 40 that form a simplified UML class diagram that includes examples of relationship definitions including both direct and indirect parent child relationships. It should be noted that a UML class diagram defines possible relationships between future instances of objects derived from at least one class definition by depicting an arrangement of relationship definitions used to define a relationship between class definitions where the possible relationships are a function of the relationship definitions. A UML class diagram is useful because the arrangement of and relationships between each of the future instances of objects derived from at least one class definition may be verified and or at least partially predicted using the UML diagram.

Generally, in an appliance runtime environment, variables 230 are identifiers which have an associated value 232 where different actors in the runtime system set the value 232 of the variable 230. However, FIG. 37 depicts additional possibilities for expanded use of variables 230 and their values 232 and illustrates the benefit of holders.

In some cases, a variable 230 can have a relationship with a value 232 where, for example, the relationship depicts a request for the variable 230 to be set to the value 232 at a future time. In other cases, a variable 230 could be associated with a plurality of values 232 in order to depict the possible values 232 of a variable 230 at some future time.

Yet in other cases, as in forking elements within a message data payload 150 or a capabilities definition, values 232 are parents of other variables 230. Relationships like this are useful to express hierarchies of choices 234, variable validation, payload validation, command validation, user interface behavior, etc. For example a hierarchy of choices 234 might have a root of question 1 with choices A and B as children, where choice A has a child of question 2 having choices of C and D as children. This hierarchy could be used to drive a wizard, such as the use and care guide 130, such that the answer to question 1 would dictate if another question would need to be asked. For example, if the answer to question 1 was choice A, then question 2 would need to be asked to get an answer of either choice C or choice D. However, if choice B was the answer of question 1, then no further questions would be necessary. Using this technique, the behavior of the wizard could be controlled by the capability definition and an answer sheet comprising the list of questions asked and the answers given could be validated using the capability definition.

Looking again at FIG. 37, the previous example illustrated by FIG. 30 can be understood in the context of the message data payload model 40C shown in FIG. 37. Also shown is that components of the message data payload model 40C extend or inherit from class definitions in variable model 40D. A message element 156 can be a variable 232 or it can be a variable holder 236. Also, choices 234 and variable definitions 238 extend a value abstract class 240.

Using the previous example of FIG. 30 and applying it the model of FIG. 37, a forking can occur when an abstract value 242, such as a choice 234, has a child of a variable 230, like a message element 156, which is shown to be a potential arrangement in that a choice 234 extends an abstract value 242 via abstract value class 240, and that abstract value 242 can have a variable 230 as a child, and that message element 156 extends or is a message element 156. These relationship definitions as shown in the simplified UML class diagram define the possibility to have message elements 156 having
children of choices 234 with those choices 234 having children of other message elements 156 as shown in FIG. 30, which shows an instance of the message data payload model 40C of FIG. 37.

[0147] However, it can be undesirable to have direct parent child relationships between variables 230 and their values 232 as shown in FIG. 30 and as allowed by the model 40D of FIG. 37. As shown in FIG. 37, a variable holder 236 can include a reference to a variable 230 and a value 232. In this way, an indirect parent child relationship can be formed as described in the second embodiment exemplifying an indirect parent child relationship (above) and as shown in the first and second occurrences of FIG. 39, where a first holder 236 holds a reference to a first parent variable 230 and a first child value 232 and a second holder 236 holds a reference to the first parent variable 230 and a second child value 232. FIG. 39 shows that by using the first and second holder objects, the first parent variable can participate in two different indirect parent child relationships; one with the first child value 232 and the other with the second child value 232.

[0148] Additionally, as shown in FIG. 37, another embodiment shows how an indirect parent child relationship can be formed. According to the figure, an instance of a variable holder 236 can also include a reference to an instance of an object that derives from the abstract value class 240, which includes value holder 244, value 232, variable definition 238, and choice 234. And an instance of value holder 244 can include a reference to an instance of an object that derives from value abstract class 240. In this way, an indirect parent-child relationship can be formed as described in the third embodiment exemplifying an indirect parent child relationship (above) and as shown in the third and fourth occurrences of the third and second hierarchies in FIG. 40, respectively, where in the third occurrence, a first variable holder has a reference to or holds a first parent variable 230 and has a reference to or holds a second value holder 244 which then has a reference to or holds a first child value 232. In this way an indirect parent child relationship is formed between the first parent variable 230 and the first child value 232 via the direct parent child relationship between the first variable holder 236 and the second value holder 244. Likewise in the second hierarchy, the first parent variable 230 is shown for a forth time in the forth occurrence (first and second occurrences from FIG. 39) in a similar indirect parent child relationship as is shown in the third hierarchy but with a second child value 232. FIG. 40 illustrates a variable 230 participating in two indirect parent child relationships where each relationship involves a different child by using variable holders 236 and value holders 244 as prescribed by the variable model 40D of FIG. 37.

[0149] Additionally, as shown in FIG. 37, the value abstract class 240 is defined as having a direct parent child relationship with variable holders 236 or variable 230. This is the enabling model relationship definition that supports the forking element of FIG. 30 as well as the relationship between Value: Wool: 4 and Attribute: Delay: Default: 0 of FIG. 38.

[0150] FIG. 37 also illustrates the model 40 for the capabilities model instance 40F of an appliance 12. FIG. 38 illustrates a capabilities model instance 40F comprising a hierarchy of variables 230 to values 232 and variables 230 to variable definitions 238 in repeating direct parent child relationships. This hierarchy known as a capabilities tree is a child of the state 246 object idle, meaning that when the appliance 12 is in an idle state, the hierarchy contained by state object idle represents the operational capabilities of the appliance 12 from a command and control perspective. From the command perspective, all valid commands can be derived by observing and interpreting the hierarchy. A command, in its simplest form, is a message that results in one appliance variable 230 being set to a value 232. The variable 230 and the value 232 together are referred to as a paired element 252 (also shown in FIG. 41). In many cases however, a valid command to an appliance 12 includes a plurality of interdependent variables 230 each having a value 232 selected from a plurality of valid values 232 and wherein the selection of the values 232 determines a portion of the other interdependent variables 230 that also must be specified with a value 232 to form a well formed command or command container 250.

[0151] As previously described in the hierarchy of choices 234 example, the appliance capabilities model 40F can be used to determine what additional interdependent variables 230 must be included in a command container 250 based on the selected value 232 of each variable 230. Command containers 250 have at least one paired element 252. A command container 250 may be validated by traversing the capability tree to observe and verify that each of the variables 230 or variable holders 236 in the command container 250 is one of a root of the tree and a parent in the tree wherein the parent is a value 232 or value holder 244 as part of the plurality of paired elements 252, to observe and verify that each paired element 252 is located at one of the root or a direct descendent of another paired element 252 connected to the root, and to observe and verify that at least one paired element 252 comprises a value 232 or value holder 244 as a leaf node of the tree. As shown in FIGS. 41 and 42, a cycle definition, then, includes a command container 250 wherein the content 20 of the command container 250 affects the cycle of operation of the appliance 12 when the appliance 12 runtime sets the variables 230 specified by the command container 250 to the values 232 specified in the command container 250. Other information included in the cycle definition can be used for graphical user interface 68 rendering and other non-control system domain purposes.

[0152] The capabilities model instance 42F of FIG. 38 is an example of using only direct parent child relationships between variables 230 and values 232. However, according to FIG. 37, a different embodiment using variable holders 236 and value holders 244 can be constructed (similar to FIG. 40) where the capabilities model instance 42F would comprise variable holders 236, variables 230, value holders 244, and values 232.

[0153] It is apparent, by observing FIG. 38, how value holders 244 and variable holders 236 could provide improvement to the compatibility of the two model instances 42D, 42F. Just as in FIG. 37, the variable model 40D provides some common base classes for use by the message data payload model 40C and the capabilities model 40. Content 20 includes variables 230 and values 232 arranged in a nested repeating hierarchy of alternate levels of variables 230 having values 232 and value having variables 230. However, because direct parent child relationships are used in the model instances 42D, 42F, herein referred to as scenario 1, there is less reuse than could be accomplished if variable holder 236 and/or value holders 244 were used as in scenario 2 and scenario 3 of FIGS. 39 and 40, respectively. Referring the variable ‘Cycle’ in the capabilities model instance 42F and the element ‘cycle’ in the message data payload model instance 42D, it can be observed that these two information elements are the same.
logical entity. In both cases, the elements refer to the memory variable 230 in the appliance runtime which corresponds to one of the selected, request, and active cycle of the appliance 12. However, the capabilities model instance 42F contains a complete validation hierarchy as exemplified by the 'Delay' variable 230 underneath the 'Wool' value 232. By contrast, the message data payload model instance 42D on the right has two hierarchies, one for the 'cycle' and one for the 'Delay' because the designer of this context made a choice to arrange the information into separate hierarchies. Therefore, because the information is in multiple hierarchies and is partitioned and organized differently, the information must be duplicated in separate information elements as shown in Scenario 1.

However, if the information were created using the previously described technique of Scenario 3 of FIG. 40, the information would not require duplication and the information elements or identifiers thereof (i.e. variables 230, values 232, message elements 156, choices 234, variable definitions 238, etc.) could be re-used throughout multiple hierarchies each have a different context. Using this approach then, the multiple contexts can leverage information from the multiple contexts because there are common or shared objects within those contexts which can be used to gather information across multiple contexts by using the shared objects as navigation objects for jumping from and jumping to different contexts. This is further explained and exemplified by FIG. 40 and the description thereof.

For example, an appliance 12 can communicate its operational capabilities to a client by sending a capabilities model instance 42F to the client. The client can then form a command container 250 and send that command container 250 back to the appliance 12. The appliance 12 can take the variables 230 from the paired elements 252 of the command container 250 and validate the command container 250 by traversing the capabilities tree as previously described. Once validated, the appliance 12 can automatically convert the command container 250 into one or more message data payloads 150 for constructing network messages to execute the command container 250 across multiple control boards communicating on the communications network 18. This automatic conversion and validation is enabled by using variable holders 236 and value holders 244 to construct the capabilities and message data payload model instances, 42F and 42D, respectively.

When variables 230 and values 232 participate in more than one hierarchy, wherein each hierarchy has a context different from the other hierarchies, it is difficult to only use direct parent child relationships. For this reason, the UML class diagram of FIG. 37 depicts a variable model 40D wherein a user 14 can use either of the at least one variable holder 236 and the at least one value holder 244 in creating at least one hierarchy of elements for content 20 independent of any relationship that may otherwise exist between the variable 230 and other elements and between the value 232 and other elements so that the variable 230 and the value 232 can be used in different contexts with different relationships while maintaining their relationship with each other via the at least one variable holder 236 and the at least one value holder 244.

FIG. 42 depicts the use of an appliance development toolkit 10 a first set of constraints creating a first set of content 20 with which a second user 14 using an appliance development toolkit 10 having a second set of constraints could use to create a cycle definition 262. As previously described a cycle definition 262 includes a command container 250 with at least one pair element 252 derived from a collection of appliance variables 230 and values 232. The appliance namespace includes a collection of uniquely identifiable and meaningful variables 230 for an appliance 12. Therefore the user 14 of the toolkit 10 with the second set of constraints could create a cycle definition 262 by selecting data from the appliance model instance 42J shown in FIG. 42, which comprises a plurality of model instances 42 used by the appliance 12, and specifically from the appliance namespace 260. As the user 14 constructs the cycle definition 262, the toolkit 10 can validate the cycle definition 262 using the capabilities model instance 42F. The user 14 can associate data about the cycle definition 262 including source identification domain data 186 which includes brand emblems and other licensable data or other data including usage text, help, and one or more identifiers of persons, consumables, and articles, and the like.

FIG. 43 illustrates the use of a document model instance 42G within a domain model instance 42H interacting with a converter 34 and interface 30 to create content 20 for display in a viewer 38. The purpose of a document model (not shown) is to enable a user 14 to use the model instance editor 32 to create and view content 20 associated with a domain model instance 42H within the system configurator 28 before final export to a content target 22. In a sense, the viewer 38 is a content target simulator 52.

A domain model (not shown) is an abstraction or model 40 associated with real world constructs like cars, buildings, trees, law, language, media, finance, and just about any topical concept imaginable without respect to non-domain concerns like formatting, language, style, persistence form and the like.

In FIG. 43 the domain model instance 42H is an ingredient substitution model and the non-domain model instance is the contained document model instance 42G shown in the dashed box. As shown, the document model instance 42G is an arrangement of objects (shown under the UTText object) including markup objects for formatting, special objects for creating spaces or punctuation, text objects for creating static content 20, and domain objects able to contribute content 20 based on their properties, functionality, and composition.

A converter 34 traverses the arrangement to create html content 20 for the internet browser based viewer 38 on the right. In this way, a user 14 can specify the behavior of the content target 22 with respect to the content 20 by creating data for simulation of the content target 22. Additionally, viewing the content 20 aids the user 14 in understanding the meaning of the domain model 40H in that a portion of the viewable content 20 is a function of the domain model 40H. Therefore the content 20 and viewer 38 together help the user 14 validate and verify the composition of the domain model 40H.

FIG. 44 depicts binding between appliance user domain data 180 and appliance control system domain data 182. As shown, a cycle outcome model instance 42I for cooking comprising a food identifier, a vessel identifier, and a doneness identifier is bound to a cycle structure 80 identified by SCF5 wherein when the content 20 is generated for the appliance 12 from the cycle outcome model instance 42I and the sequence model instance for a cycle 42B, and appliance control functionality of FIG. 8 is created by the appliance software framework 104 of FIG. 7 and FIG. 28. A user 14 can affect the cycle of operation by selecting elements of the user
interface domain data 184 rendered on the user interface 68 and bound to the cycle structure 80 identified by SCF 5.0163. In this way, the graphical user interface 68 of FIG. 46 can display the source identification domain data 186 and other data on the user interface 64 of the appliance 12 in response to the identifiers either sensed from a sensor like a scanner or selected via the appliance user interface 64. Moreover, as previously discussed, the cycle definition 262 can be automatically translated into transmittable network messages 266 by a message generator 264 of FIG. 45 using the message data payload model instance 42D of FIG. 42 and FIG. 45.

0164. FIG. 47 shows an example of how an appliance development toolkit 10 according to the invention is used in interaction with a user 14 and an appliance 12 to diagnose an appliance 12. It further shows additional examples of the use of a constrained toolkit 10 using model instances 42 as the constraining component. The toolkit 10 is configured to create one or more test scripts 270 having at least two steps, each step being separated from its adjacent steps by a transition condition that includes a logic expression resolvable to a Boolean transition value, at least one command statement associated with one of the at least two steps that instructs what should happen when the at least one step is the current step so that a test engine can execute the at least one command statement contemporaneous with the transition of the at least one step from the current step to the next step. The toolkit 10 also provides information associated with at least one message element 156 in a message data payload 50 so that the message data payload 50 is uniquely identifiable within a universe of pre-defined message data payloads 50 for the appliance 12. (See the foregoing discussion of identifiers.) A converter 34 will place the test script 270 into a form to be readable or at least usable in diagnosing an appliance 12.

0165. There will be associations of command statements and message elements 156 created by the toolkit 10 so that a test engine application 50A can create a command container 250 based on the test script. Command statements will include such things as questions to a user such as shown in FIGS. 11-15. Holders 236, 244 as discussed elsewhere are useful tools for the editor 10 to effect flexibility in creating command sequences for the test script 270. The test engine application 50A is configured to observe subsequent network messages 266 and relate those to a transition logic in the test script 270 and to evaluate the logic for transition to the next step as it traverses a hierarchy in the test script 270.

0166. In one embodiment, a second a communications driver can be configured to establish a communication link with the test engine application 50A, and a fault tree tool application 50B is configured to access one or more fault trees 110 to construct a command container 250 on instructions in the fault tree(s) 110 and to convey the command container 250 to the test engine application 50A via the second communication link during execution of a command statement in the fault tree 110.

0167. So it can be seen that a model instance editor 32 can use the message data payload model instance 42D to create the data that a model instance editor 32 uses, along with a sequence model instance for tests 42K, to create the test script (which is a sequence model instance variant). The test engine application 50A uses the test script 270 in communication with a smart coupler 56, such as a smart cable, to communicate with the appliance 12 and with the user 14. Meanwhile a model instance editor 32 uses a sequence model instance for a fault tree 42C to create a sequence model instance variant, such as a fault tree, that a fault tree tool application 50B uses in interaction with the user 14.

0168. A sequence model instance for tests 42K is similar to other instances using the sequence model 40B in that it allows the user 14 to create a set of steps separated by transition conditions having logic to drive the condition where each step has an associated action specifying the tasks to be done in that step. A sequence model instance for tests 42K can use message data payload model instances 42D to constrain elements for the actions in each step. This is accomplished in a similar fashion previously described for FIG. 27 wherein the message data payload model instance 42D is used to constrain a sequence model instance for a cycle 42B.

0169. Referring back to FIG. 47, the sequence model instance for a fault tree 42C is constrained as well using the sequence model instance for tests 42K wherein each test in the sequence model instance for tests 42K might have an identifier or an identifying test object that can be bound to the action of a step in the sequence model instance for a fault tree 42C at tool time such that when the fault tree tool application 50B reaches a step wherein a test script 270 should be executed, it can communicate with the test engine application 50A to invoke the test script 270 corresponding to the identification of the test object at runtime.

0170. The test engine application 50A, having been previously constrained by elements from the message data payload model instance 42D and having actions of steps bound to message data payload model instances 42D can use the binding to automatically construct and transmit useable messages 266 from the test engine application 50A to the appliance 12 using the method as previously described for cycle definition 262 translation to message data payloads 150.

0171. FIGS. 48, 48A, and 48B illustrate binding between multiple instances of user domain data 180 to control system domain data 182, which is illustrated at a high level in FIG. 23. The control system domain data 182 comprises a cycle outcome model instance 42I, 42J and a sequence model instance for a cycle 43B that can be used for a cycle structure 80 for a cooking appliance 12. To achieve a desired outcome, a set of cooking profiles (FIG. 44) are created each having multiple components specifying various parameters associated with the cooking cycle.

0172. To get the doneness of crispy donuts, the profiles in FIG. 44 indicate that the user 14 needs to use an iron skillet in a 30° cavity, and in the other case we have a glass crock pot in a 27° cavity; thus, a user 14 can cook those donuts differently to achieve the same outcome, and the desired cycle outcome will point to the specific sequence for the cycle. Different profiles and different cycle structures 80 can therefore achieve the same outcome given a set of appliance user domain data 180 elements like the food type, cavity size, and the pan.

0173. Using the recipe specified by one of the sequence model instance for a recipe with a first set of portions 42L and the sequence model instance for a recipe with a second set of portions 42M, the selection of which is based on the cooking profiles, the user 14 first gets the ingredients. In this example, the user 14 is using the sequence model instance for a recipe with a first set of portions 42L; get 5 ounces of flour, 2 ounces of sugar. The sequence model instance for a recipe with a first set of portions 42L then transitions to the next state 246 called mix. The user 14 then mixes the ingredients and transitions to the next state to cook. The user 14 puts the mix in the pan and forms the dough, gets a pan, places the dough in the donut
forms in the pan, and then transitions into state cook, where the user 14 places the pan in the appliance 12 and uses the user interface 46 to select the food pan and doneness to select the cycle.

[0174] The ingredients substitution model 40N and instance 42N thereof are both appliance user domain data 180. For a portion of flour, there is an alternate portion of crushed seaweed, and a substitution object in the ingredients substitution model instance 42N holds the primary and alternate portion and enables a user 14 to substitute one for the other and still complete the desired cooking cycle.

[0175] Likewise, we have a second substitution that shows a substitution between sugar and Splenda. So the arrows between the ingredients and the alternate portions and the substitution window point up to both the sequence model instance for a recipe with a first set of portions 42L and the sequence model instance for a recipe with a second set of portions 42M, and as seen in the sequence model instance for a recipe with a second set of portions 42M, the ingredients automatically changed out the ingredients from 5 ounces of flour to 60 ounces of crushed seaweed and from 2 ounces of sugar to 4 ounces of Splenda. This relationship between these models/model instances enables the user 14 to fluidly accommodate issues that arise during cooking.

[0176] The alternate portion can also have nutritional information associated therewith so that as sequence model instance for recipes call for certain portion substitutions, the nutritional information is derived from the portions and then compared to the constraints from the meal planner discussed below, allowing the meal planner to then actually achieve the substitutions based on nutritional constraints.

[0177] As shown in FIG. 48, this ability to transform and suggest a recipe comprises a meal planner that can query other smart agents of information to figure out how to best plan the meal. The meal can also be a combination of multiple recipes, such as a lasagna followed by donuts for dessert. The meal planner will thus query for the participants in the meal, each person’s schedules, the profiles of the participants to note food preferences, allergies, diets, and doctor’s orders that would create constraints on the meal planner. The meal planner will then use the information garnered from these queries to select either certain recipes or certain ingredients for recipes to conform to the preferences of the people, the schedules of the people, or the nutritional constraints that people might have based on their diets, allergies, etc.

[0178] The other constraint that a meal planner could look at would be an inventory system constraint where an inventory system actually knows the available portions that are in the house and then the meal planner could take that and select recipes or do ingredient substitutions or recipes based on the inventory at hand. It could also populate a shopping list if there were certain things that it highlighted as not being available or being in conflict with a preference of a person or a diet of a person, then it could kind of spit out a shopping list and say to the user of the meal planner, hey, we better get this. And of course it could automate that transaction by having it ordered, delivered, etc.

[0179] While the invention has been specifically described in connection with certain specific embodiments thereof, it is to be understood that this is by way of illustration and not of limitation, and the scope of the appended claims should be construed as broadly as the prior art will permit.

We claim:
1. A meal planning system comprising:
   memory having appliance user domain data and control system domain data, wherein at least one instance of appliance user domain data is bound to at least one instance of control system domain data or at least one instance of other appliance user domain data, the appliance user domain data and the control system domain data being related to planning and preparing at least one meal,
   a communication path connected to the memory and connectable to a data sender
   wherein a query associated with criteria data referencing at least a portion of one of the control system domain data or the other appliance user domain data from the data sender to the memory over the communication path will return data including at least a portion of the at least one instance of appliance user domain data to the data sender so that the data sender can use the return data to affect the planning and preparing of the at least one meal.

2. The meal planning system of claim 1 further comprising a processor having a meal planning software engine, wherein the meal planning software engine is configured to interact with the memory to manage the planning and preparation of at least one meal.

3. The meal planning system of claim 2 further comprising a user interface in communication with the processor and the memory wherein a user can interact with the meal planning software engine.

4. The meal planning system of claim 1 wherein the appliance user domain data includes recipe domain data comprising at least one of ingredients, preparation instructions, purchasing instructions, and meal serving instructions.

5. The meal planning system of claim 4 wherein the other appliance user domain data includes ingredient substitution domain data comprising at least two sets each having an ingredient, a quantity, and a unit which are equivalent and substitutable with respect to the recipe domain data wherein the meal planning system can alter the meal plan when the criteria data from the data sender includes information from the other appliance user domain.

6. The meal planning system of claim 6 wherein the criteria data includes information from the ingredient substitution domain wherein the meal planning system can alter at least one of ingredients and ingredient portions associated with the at least one meal in response to the criteria data.

7. The meal planning system of claim 6 wherein the criteria data includes at least one identifier representing one of a participant of a meal, a profile of a meal participant, medical information about a participant, dietary needs of a participant, allergies of a participant, preferences of a participant, schedule of a participant, current ingredient inventory, and historical information.

8. The meal planning system of claim 1 wherein the criteria data includes at least one of the number of participants of a meal, medical information, dietary needs, allergies, preferences, and schedule wherein the meal planning system can alter at least one of ingredients and ingredient portions associated with the at least one meal in response to the criteria data.

9. The meal planning system of claim 8 wherein the other appliance user domain data includes nutrition domain data comprising nutritional information.
10. The meal planning system of claim 9 wherein the criteria data includes at least one of nutritional information, medical information, dietary needs, allergies, and preferences.

11. The meal planning system of claim 9 configured to transform the meal plan in response to criteria data including ingredient information and in further response to nutrition information.

12. The meal planning system of claim 6 wherein the criteria data includes ingredient inventory data including information relating to the quantity or amount of foods and ingredients related to meal planning.

13. The meal planning system of claim 1 further configured to affect one of the appliance user domain data and the control system domain data in response to the binding.

14. The meal planning system of claim 13 wherein the appliance user domain data includes schedule domain data including a portion of at least one schedule, and the control system domain data includes meal preparation plan information including duration information, wherein the affect is to change at least one of the portion and the plan to make the portion and the plan compatible with respect to schedule and duration.

15. The meal planning system of claim 1 further comprising a cooking appliance having at least one control board connected to the communication path, wherein the at least a portion of the at least one appliance user instance is returned to the control board so that the bound control system domain data will affect operation of the control board.

16. The meal planning system of claim 15 wherein elements of the at least one appliance user instance include cooking vessel identifiers.

17. The meal planning system of claim 15 wherein elements of the at least one appliance user instance include cooking outcome identifiers.

18. The meal planning system of claim 15 further comprising a processor having a meal planning software engine, wherein the meal planning software engine is configured to interact with the memory to manage the planning and preparation of at least one meal, and further comprising a graphical user interface wherein a user can interact with the meal planning engine and initiate the query.

19. The meal planning system of claim 1 wherein the at least one control system instance includes a portion of the operational capabilities of at least one appliance wherein the meal planning system can alter the meal plan in response to receiving criteria data from the data sender including information about the available appliances for use in the preparing of at least one meal.

20. The meal planning system of claim 19 wherein the at least one control system instance includes a portion of the available appliances.

21. The meal planning system of claim 19 further comprising a graphical user interface wherein a user specifies a portion of the available appliances.

22. The meal planning system of claim 19 further comprising a communication path connectable to at least one appliance wherein a portion of the available appliances is determined using the communications path.

23. The meal planning system of claim 22 wherein the portion of the available appliances is determined using the communications path via discovery message.

24. The meal planning system of claim 19 wherein the altered meal plan is changed relative to the time domain in response to the available appliances.

25. The meal planning system of claim 19 wherein the altered meal plan is changed relative to the cycles to be used on each of the available appliances.

26. The meal planning system of claim 19 wherein the altered meal plan is changed relative to the associations between the available appliances and at least one task included in the meal plan.

27. The meal planning system of claim 26 wherein the at least one task is selected from at least one of baking, broiling, convection, cleaning, washing, chilling, mixing, blending, chopping, frying, simmering, boiling, freezing, cooling, chilling, warming, maintaining temperature, keeping warm, and microwaving.

28. The meal planning system of claim 19 further comprising a communication path connectable to at least one appliance, wherein the meal planning system is configured to send instructions to the at least one appliance in response to the meal plan.

29. The meal planning system of claim 28 wherein the instructions are one of a cycle definition and a command container.

30. The meal planning system of claim 28 wherein the instructions are derived from the operational capabilities of the at least one appliance.

31. The meal planning system of claim 30 wherein the operational capabilities are retrieved from the at least one appliance via network message.

32. An appliance user domain data system to enable at least one appliance user domain related application comprising: memory having appliance user domain data and control system domain data, wherein at least one instance of appliance user domain data is bound to at least one instance of control system domain data or at least one instance of other appliance user domain data, the appliance user domain data and the control system domain data being related to planning and preparing at least one user domain related activity, a communication path connected to the memory and connectable to a data sender wherein a query associated with criteria data referencing at least a portion of one of the control system domain data or the other appliance user domain data from the data sender to the memory over the communication path will return data including at least a portion of the at least one instance of appliance user domain data to the data sender wherein the data sender can use the return data to affect the planning and preparing of the at least one domain related activity.

33. The appliance user domain data system of claim 32 wherein the domain related activity is one of shopping, buying household goods, cooking, laundry, cleaning, and storage.
