Low drift, rainfastness, high uptake and ULV tank mix adjuvant formulation

The instant invention refers to a tank mix adjuvant formulation comprising providing improved drift, high uptake and rainfastness to an agrochemical formulation comprising at least one agrochemical pesticide. Further the invention is directed to the tank mix of an agrochemical formulation comprising at least one pesticide with the adjuvant combination, as well as the use of both the adjuvant formulation and the ready tank mix for ULV applications and conventional spray volume applications.

The efficient foliar application of agricultural products for controlling disease infections, insect infestations and weeds is an important contributor for the supply of sufficient food for the increasing population in our world. This is commonly achieved by spray application of a dilution of the agricultural product in water. However, the spray application process is not always very efficient, with possible off-target losses occurring from drift of fine spray droplets, poor retention from spray droplets bouncing off and rolling off leaf surfaces, poor wetting and coverage on the target plants, poor uptake of active ingredients into the target plants, and wash-off of the active ingredient by rainfall. There is therefore a need to improve the efficiency of spray application of agricultural products onto target plants.

The solution is found by a combination of materials that can be formulated as an adjuvant formulation (also referred to as adjuvant mixture or adjuvant combination or adjuvant composition) that can be added to the spray dilution of the agricultural products to reduce off-target drift, increase the retention on leaves, increase the wetting, coverage and uptake, and reduce the wash-off by rainfall. Furthermore, it is especially important that the adjuvant mixture is effective at low spray volumes (typically less than or equal to 25 to 50 l/ha depending on the crop canopy density, and extending up to 50 to 80 l/ha for orchards) where application technologies such as unmanned aerial vehicles (UAV), unmanned ground vehicles (UGV) and low spray volume boom spray vehicles can provide lower CO₂ emissions. Furthermore, it is important that the adjuvant mixture does not produce high levels of foam, especially at low spray volumes.

Another aspect of the instant invention is the reduction of foam or foaming, which in particular in highly concentrated formulations comprising a relatively high amount of surfactants is an issue.

The present invention relates to adjuvant compositions for tank-mixture with crop protection products: their use for foliar application; their use at low spray volumes; their use by unmanned aerial systems (UAS), unmanned guided vehicles (UGV), and tractor mounted boom sprayers fitted with conventional nozzles but also pulse width modulation spray nozzles or rotating disc droplet applicators; and their application for controlling agricultural pests, weeds or diseases, in particular on waxy leaves.

Modern agriculture faces many challenges in producing sufficient food in a safe and sustainable way. There is therefore a need to utilise crop protection products to enhance the safety, quality and yield while minimising the impact to the environment and agricultural land. Many crop protection products, whether chemical or biological, are normally applied at relatively high spray volumes, for example in selected cases >50 L/ha, and often >150-400 L/ha. A consequence of this is that much energy must be expended to carry the high volume of spray liquid and then apply it to the crop by spray application. This can be performed by large tractors which on account of their weight and also the weight of the spray liquid produce CO₂ from the mechanical work involved and also cause detrimental compaction of the soil, affecting root growth, health and yield of the plants, as well as the energy subsequently expended in remediating these effects.

Moreover, when applying such spray formulations, a more or less pronounced drifting of the spray solution containing the active substance(s) may be observed, depending on the wind conditions, nozzle type, and other application parameters such as, for example, nozzle pressure, boom height, and tractor speed.

Pesticide spray drift is a major source of concern in relation to the environmental impact of agriculture on natural ecosystems and urban areas. Furthermore, this drift is undesirable because it causes a certain part of the applied agrochemical to be lost as far as the intended application rate of the treated area is concerned.

5 More importantly, the drifting material might cause damage to neighbouring crops and especially, have effects on the local environment (e.g., surface water, non-target flora and fauna) as well as bystanders and occupants in residential areas.

There is a need for a solution that significantly reduces the drift of the active ingredients / formulations, both when sprayed, while at the same time preferably reducing high volumes of spray liquid and 10 reducing the weight of the equipment required to apply the product.

Various methods are used to prevent the drifting of the spray outside the field borders. The use of natural or artificial windbreaks is well known. However, it has been described that even when such screens are used, drift can cause deposition of the active substances behind such borders (e.g., "Deposition of spray drift behind border structures", M. De Schamphelleire et al. Crop Protection 28 (2009) 1061-1075).

15 Another frequently used drift mitigation measure is buffer zones, either off-crop or in-crop. A disadvantage of off-crop buffer zones is that part of the field cannot be sown with a crop, an economic cost to the farmer. A disadvantage of in-crop buffer zones is that part of the crop is not protected adequately, resulting in a lower yield and perhaps resistance development. Clearly, this is something farmers want to prevent.

20 Next to physically limiting spray drift, it is also possible to alter the structure of the spray cloud so that less drops are prone to drift – i.e., typically those drops prone to drift have a diameter under 100 μm . This can be done by choosing different types of nozzles, changing the pressure at which the spray cloud is produced, or by changing the properties of the spray liquid itself. Especially changing nozzles and / or nozzle pressure is something farmers do not prefer to do because it is time consuming and makes the 25 production of their crop more expensive. Also, the equipment necessary on sprayer to deal with variable application rates is not common. For these reasons, a more acceptable way to optimise a spray cloud, so that it leads to less or more limited drift, is by adjusting the properties of the spray liquid.

Although other factors such as meteorological conditions and spray boom height contribute to the potential for drift, spray droplet size distribution has been found to be a predominant factor. Teske et. 30 al. (Teske M. E., Hewitt A. J., Valcore, D. L. 2004. The Role of Small Droplets in Classifying Drop Size Distributions ILASS Americas 17th Annual Conference: Arlington VA) have reported a value of < 156 microns (μm) as the fraction of the spray droplet distribution that contributes to drift. Other researchers consider droplets with diameter < 150 μm to be most drift-prone (J. H. Combellack, N. M. Westen and R. G. Richardson, Crop Prot., 1996, 15, 147–152, O. Permin, L. N. Jørgensen and K. 35 Persson, Crop Prot., 1992, 11, 541 – 546). Another group H. Zhu, R. W. Dexter, R. D. Fox, D. L. Reichard, R. D. Brazee and H. E. Ozkan, J. Agric. Engineering Res., 1997, 67, 35–45.) cites a value of < 200 μm as the driftable fraction. Based on theoretical studies and computer simulations, spray droplets with diameter < 100 μm have been identified as the most drift-prone (H. Holterman, Kinetics and evaporation of water drops in air, 2003, IMAG Report 2003-12; P. A. Hobson, P. C. H. Miller, P. J. 40 Walklate, C. R. Tuck and N. M. Western, J. Agr. Eng. Res., 1993, 54, 293–305; P. C. H. Miller, The measurement of spray drift, Pesticide Outlook, 2003, 14, 205–209). A good estimation of droplet size likely to contribute to drift, therefore, is the fraction below about 100 μm (driftable fraction). The smaller the droplets the longer is the residence time in the air and the higher is the tendency to evaporate and / or to drift rather than deposit within the field borders. A way to minimize the drift effect is by 45 adding suitable drift control agents to pesticide formulations that increase the size of the droplets in the spray cloud – i.e., shift the droplet spectra towards larger droplets. When searching for solutions to overcome the drift problem, it has to be taken into account that the biological performance of the

resulting application is not reduced. The use of formulation (both in-can and tank-mix) that increase the spray droplet size may reduce the efficacy to some extent, mainly because of reduced cover (e.g., “Biological efficacy of herbicides and fungicides applied with low-drift and twin-fluid nozzles” P.K.Jensen et al. Crop Protection 20 (2001)57-64). Retention of larger droplets on leaf surfaces can be

5 reduced as they run-off or bounce or shatter and redistribute. Fewer larger droplets adhering to the leaf surface can reduce overall biological efficacy. Furthermore, for crops where the spray cloud has to penetrate into the canopy of the crop, very large droplets can pass directly through canopies, or bounce off leaves, or shatter and redistribute to soil. All these effects of applying active compound in large droplets may add to reduced efficacy.

10 It also has to be taken into account that many compounds added to a formulation to improve efficacy, storage and other important properties often have a negative effect on drift properties of the spray broth, i.e. tend to reduce droplet size or enhance evaporation afterwards.

15 There is a need for a solution that significantly reduces the high volumes of spray liquid and reduces the weight of the equipment required to apply the product.

20 In agriculture, low spray volume application technologies including unmanned aerial systems (UAS), unmanned guided vehicles (UGV), and tractor mounted boom sprayers fitted with pulse width modulation spray nozzles or rotating disc droplet applicators are offering farmers solutions to apply products with low spray volumes, typically down to 10 to 20 l/ha or less. These solutions have advantages including for example that they require significantly less water which is important in regions where the supply of water is limited, require less energy to transport and apply the spray liquid, are faster both from quicker filling of the spray tank and faster application, reduce the CO₂ generation from both the reduced volume of spray liquid to transport and from the use of smaller and lighter vehicles, reduced soil compaction damage, and enabling the use of cheaper application systems.

25 However, Wang *et al* [Field evaluation of an unmanned aerial vehicle (UAV) sprayer: effect of spray volume on deposition and the control of pests and disease in wheat. *Pest Management Science* 2019 doi/epdf/10.1002/ps.5321] demonstrated that as the spray volume is decreased from 450 and 225 l/ha to 28.1, 16.8 and 9.0 l/ha, the coverage (% area), number of spray deposits per area, and diameter of the spray deposits as measured on water sensitive paper all decreased (see Table 3 in Wang *et al*, 2019).
30 In parallel, the biological control efficacy for both wheat aphid control and powdery mildew control decreased at low spray volumes with the greatest decrease observed at 9.0 l/ha, followed by 16.8 l/ha (see Figures 6, 7 and 8 in Wang *et al*, 2019).

35 There is therefore a need to design formulation systems that overcome the reduction in the coverage and diameter of the spray deposits at low spray volumes even through the number of spray deposits per area is decreasing: as the spray volume decreases, the number of spray droplets per unit area decreases proportionately for the same spray droplet spectra size. This is especially necessary below 25 l/ha, more especially below 17 l/ha, and even more especially at 10 l/ha and below.

40 Moreover, due to an increase in concentration of adjuvants in the spray solution to enhance the uptake into the plant, there is a higher chance for wash-off of the spray solution due to the higher local concentration of adjuvants.

Also, higher concentrations of surfactants in low spray volume formulations and spray broths usually lead to a smaller droplet size which in turn increases drift.

45 Therefore, there is a need to provide formulations which, when sprayed not only at “normal” volumes (50-500 l/ha) but also at ultra-low spray volumes according to the present invention, show a low drift while at the same time have a good or acceptable uptake.

The solution is provided by adjuvant formulations according to claim 1 and specifically by formulations containing specific drift reducing agents in combination with selected uptake agents at specific concentrations. Such formulations provide minimized or at least maintained drift while simultaneously

5 providing increased coverage and increased diameter of spray deposits at low spray volumes, while maintaining or improving uptake and thus biological efficacy. Furthermore, the increased coverage and increased diameter of spray deposits is comparable to the coverage obtained at normal higher spray volumes.

Moreover, the formulations exemplifying the invention are particularly effective on hard to wet leaf
10 surfaces where more conventional spray volumes have poor retention and coverage.

For low volume applications a particular advantage of the invention stemming from the low total amount of all ingredients compared to the level required at normal higher spray volumes is lower cost of formulations and their ease of production. Further advantages include improved formulation stability and simplified manufacture, less cost of goods as well as less impact on the environment.

15 Formulations, also for tank mixes, known in the prior art containing drift reducing agents are principally designed for much higher spray volumes and generally contain lower concentrations of uptake enhancing agents in the spray broth. Nevertheless, due to the high spray volumes used in the prior art, the total amount of agents used and therefore in the environment is higher than according to the present invention.

20 The concentration of the drift reducing agents is an important element of the invention, since in particular for oil based drift retardants, which also are used as penetration enhancers, suitable effects occur already at much lower concentrations than any effect on the penetration of actives. Thus, with low amounts of said oils and little impact on the environment drift can be reduced significantly. "Low amounts of said drift reducing agents (also referred to as drift retardants) means less than 25 g/l. This means, that already with an amount of 5 to 10 g/ha good drift reduction can be achieved instead of conventional 100 – 500 g/ha, which has to be present for an uptake effect.

25 On the other hand, high oil contents increase volume of product, manufacture complexity and can decrease product stability, thus they should be avoided if not necessary as uptake enhancer or solvent.

The minimum concentration of drift reducing agents is achieved, normally at 0.5. g/l.

30 With regard to the uptake agents in low volume applications, in a spray volume of 500 l/ha as it is used in the prior art, about 250 g/ha of uptake agents would be required to achieve suitable uptake. Hence, faced with the task to reduce the spray volume, the skilled person would apply the same concentration of uptake agents in the formulation. For example, for a spray volume of 10 l/ha about 5 g/ha (about 0.05% in the spray broth) uptake agent would be required. However, at such a low volume with such 35 low concentration of uptake agents sufficient uptake cannot be achieved (see examples).

Moreover, as pointed out above, according to the present invention, uptake enhancers have to be present to enable uptake of the active ingredients into the plants to enhance biological efficacy.

40 As has been shown in prior applications, we have found that increasing the concentration of uptake agents as the spray volume decreases can compensate for the loss in coverage (due to increased uptake) from the reduction in spray volume. It was surprisingly found that for every reduction of the spray volume by 50%, the concentration of uptake agent should roughly be doubled.

Thus, although the absolute concentration of the uptake agents is increased compared to ready mix formulations known in the art, the relative total amount per ha can be decreased, which is advantageous, both economically and ecologically, while coverage by and efficacy of the formulation according to the

invention is improved, maintained or at least kept at an acceptable level when other benefits of the low volume applications are considered, e.g. less costs of formulation due to less cost of goods, smaller vehicles with less working costs, less compacting of soil etc.

5 Further, we have surprisingly found that the formulations according to the present invention show low drift, and an comparable or enhanced uptake of active ingredient when compared to formulations without drift retardant agents known in the art.

It also has been found, that despite the high concentration of uptake agents (uptake enhancers), the drift reduction of the formulations according to the present invention is also comparable or better than those of the reference formulations based on the prior art.

10 Further, it was found that when methyl esters of vegetable oils are used as b), there is also a positive effect observed on foaming.

As pointed out above, the formulations of the present invention are particularly suited for low volume applications depending on the leaf surface texture. Bico *et al* [Wetting of textured surfaces, Colloids and Surfaces A, 206 (2002) 41-46] have established that compared to smooth surfaces, textured surfaces 15 can enhance the wetting for formulation spray dilutions with contact angles $<90^\circ$ and reduce the wetting for contact angles $>90^\circ$.

This is also the case for leaf surfaces, in particular textured leaf surfaces, when sprayed in a method according to the invention.

20 Textured leaf surfaces include leaves containing micron-scale wax crystals on the surface such as wheat, barley, rice, rapeseed, soybean (young plants) and cabbage for example, and leaves with surface textures such as lotus plant leaves for example. The surface texture can be determined by scanning electron microscope (SEM) observations and the leaf wettability determined by measuring the contact angle made by a drop of water on the leaf surface.

25 In summary, the object of the present invention is to provide an adjuvant formulation which can be applied in ultra-low volumes, i.e. < 20 l/ha, while still providing good leaf coverage, uptake and biological efficacy against fungicidal pathogens, weeds and pests, and providing good rain-fastness, and at the same time reducing the amounts of additional additives applied per ha, as well as a method 30 of using said formulation at ultra-low volumes (< 20 l/ha), and the use of said formulation for application in ultra-low volumes as defined above.

35 Most preferred the carrier is water.

These spray liquids are applied by customary methods, i.e., for example, by spraying, pouring or injecting, in particular by spraying, and most particular by spraying by UAV.

The application rate of the formulations according to the invention can be varied within a relatively wide range. It is guided by the particular active agrochemicals and by their amount in the formulations.

With the aid of the formulations according to the invention it is possible to deliver active

5 agrochemical to plants and/or their habitat in a particularly advantageous way.

The present invention is also directed to the use of agrochemical compositions according to the invention for the application of the agrochemical active compounds contained to plants and/or their habitat.

With the formulations of the invention it is possible to treat all plants and plant parts. By plants here 10 are meant all plants and plant populations, such as desirable and unwanted wild plants or crop plants (including naturally occurring crop plants). Crop plants may be plants which can be obtained by conventional breeding and optimization methods or by biotechnological and gene-technological methods or combinations of these methods, including the transgenic plants and including the plant 15 cultivars which can or cannot be protected by varietal property rights. By plant parts are to be meant all above-ground and below-ground parts and organs of the plants, such as shoot, leaf, flower and root, an exemplary listing embracing leaves, needles, stems, trunks, flowers, fruit bodies, fruits and seeds and also roots, tubers and rhizomes. The plant parts also include harvested material and also 20 vegetative and generative propagation material.

What may be emphasized in this context is the particularly advantageous effect of the formulations 25 according to the invention with regard to their use in cereal plants such as, for example, wheat, oats, barley, spelt, triticale and rye, but also in maize, sorghum and millet, rice, sugar cane, soya beans, sunflowers, potatoes, cotton, oilseed rape, canola, tobacco, sugar beet, fodder beet, asparagus, hops and fruit plants (comprising pome fruit such as, for example, apples and pears, stone fruit such as, for 30 example, peaches, nectarines, cherries, plums and apricots, citrus fruits such as, for example, oranges, grapefruits, limes, lemons, kumquats, tangerines and satsumas, nuts such as, for example, pistachios, almonds, walnuts and pecan nuts, tropical fruits such as, for example, mango, papaya, pineapple, dates and bananas, and grapes) and vegetables (comprising leaf vegetables such as, for example, endives, corn salad, Florence fennel, lettuce, cos lettuce, Swiss chard, spinach and chicory for 35 salad use, cabbages such as, for example, cauliflower, broccoli, Chinese leaves, *Brassica oleracea* (L.) *convar. acephala var. sabellica* L. (curly kale, feathered cabbage), kohlrabi, Brussels sprouts, red cabbage, white cabbage and Savoy cabbage, fruit vegetables such as, for example, aubergines, cucumbers, capsicums, table pumpkins, tomatoes, courgettes and sweetcorn, root vegetables such as, for example celeriac, wild turnips, carrots, including yellow cultivars, *Raphanus sativus* var. *niger* and var. *radicula*, beetroot, scorzonera and celery, legumes such as, for example, peas and beans, and 40 vegetables from the *Allium* family such as, for example, leeks and onions.

The treatment of the plants and plant parts in accordance with the invention with the inventive 45 formulations is carried out directly or by action on their environment, habitat or storage area in accordance with the customary treatment methods, for example by dipping, spraying, vaporizing, atomizing, broadcasting or painting on and, in the case of propagation material, especially seeds, additionally by single or multiple coating.

The active agrochemicals comprised develop a better biological activity than when applied in the form of the corresponding conventional formulations.

If not otherwise defined in this application, the molecular weight refers to the weight-average 45 molecular weight Mw which is determined by GPC in methylene chloride at 25 °C with polystyrene as the standard.

Experimental methods

Method 1: Method of preparation of recipes

5 The components were added to a vessel in the following order with stirring until homogeneous, carriers and other formulants (e), rain-fast additive (b), uptake enhancing additive (d) and then drift reducing additive (a).

Method 2 : Description for Fungicide Greenhouse tests

10 Seeds were laid out in “peat soil T” in plastic pots, covered with soil and cultivated in a greenhouse under optimum growth conditions. Two to three weeks after sowing, the test plants were treated at the one- to two-leaf stage. The test fungicide formulations were prepared with different concentrations and sprayed onto the surface of the plants using different water application rates: 200 l/ha as a standard conventional rate and 15 l/ha as an ultra-low-volume (ULV) application rate. The nozzle type used for 15 all applications was TeeJet TP 8002E, used with 2 bar and 500 - 600 mm height above plant level. Cereal plants were put in an 45° angle as this reflected best the spray conditions in the field for cereals. The ULV application rate was achieved by using a pulse-width-modulation (PWM) system attached to the nozzle and the track sprayer device at 30Hz, opening 8% - 100% (10 l/ha – 200 l/ha spray volume).

20 In a protective treatment the test plants were inoculated 1 day after the spray application with the respective disease and left to stand in the greenhouse for 1 to 2 weeks under optimum growth conditions. Then, the activity of the fungicide formulation was assessed visually.

In curative conditions plants were first inoculated with the disease and treated 1-3 days later with the fungicide formulations. Visual assessment of the disease was done 3-9 days after application of formulations (dat).

25 The practices for inoculation are well known to those skilled in the art.

Method 3 : Leaf wash-off

30 Apple or corn leaf sections were attached to a glass microscope slide. To this 0.9 to 1.4 µl drops of the different formulations diluted at the spray dilution in deionised water containing 5% CIPAC C water and a small amount of fluorescent tracer (Tinopal OB as a micron sized aqueous suspension) were applied with a micropipette and left to dry for 1 hour. Under UV illumination (365nm) the leaf deposits were imaged by a digital camera. The leaf sections were then held under gently running deionised water (flow rate approximately 300ml/minute at a height 10cm below the tap outlet) for 15s. The leaf sections 35 were allowed to dry and the deposits were re-imaged and compared to the original images. The amount of active ingredient washed off was visually estimated between 5 with most remaining and 1 with most removed. Three or more replicates were measured and the mean value recorded.

Method 4: Coverage (pipette)

Greenhouse plants in the development stage as indicated in Tables M1a & M1b were used for these experiments. A 1.4 μ l drop of spray liquid containing a small amount of fluorescent tracer (Tinopal OB as a micron sized aqueous suspension) was pipetted on top without touching the leaf surface and 5 left to dry. Under UV illumination (365nm) the leaf deposits were imaged by a digital camera and the area of the deposits measured using ImageJ software (www.fiji.com).

Method 5: Drift filter paper deposits

10 The formulations were diluted in water to the required concentration with a small amount of a fluorescent tracer (Tinopal SC), sprayed through a TeeJet 11002E nozzle at a pressure of 2 bar onto filter paper and the droplet size spectra measured using ImageJ.

The filter paper is photographed using a digital camera, with UV light [365nm] as the illuminating resource. In the pictures of filter paper, droplet deposits which are fluorescently labelled have much higher intensity than the filter paper and other background.

15 Images are processed in the ImageJ software (www.fiji.com). First, the RGB image is split into Red, Green and Blue channel, only the Green or Blue channel is used for further analysis, depending on the intensity of the original image. Next, the 'Subtract background' algorithm is applied to the single channel image to remove background noise, which in turn improve the contrast between the droplet deposits and the background. Afterward, an intensity threshold is generated automatically and applied 20 by the software, resulting in a binary image where droplet deposits are remained with maximum intensity while the background such as the filter paper itself has zero intensity. Finally, the 'watershed' algorithm is applied to the binary image, in order to segment droplets that are connected in the image. All remained and segmented objects are detected and labelled with their positions and sizes. The size of each object represents the area of each deposit, is in the unit of μm^2 .

25 The nozzle used in the spray test has a VMD of 210 μm with water. The Volume Median Diameter (VMD) is determined from the cumulative distribution functions (CDFs) of droplet volume V, droplets that have sizes smaller than VMD account for 50% of the total sprayed volume. Since there is 30 no direct correlation between the deposit area obtained from filter paper and the actual droplet size/volume, the VMD of water has been used as a reference to rescale the CDFs of formulation sprays.

35 From ImageJ analysis, the area (A) of each droplet deposit on filter paper is recorded. The diameter of each deposit $d_A = (4A/\pi)^{1/2}$, the estimate droplet volume $V_{\text{estimate}} = \pi \cdot d_A^3/6$. The CDF of the basic formulation is plotted using the estimate droplet volume V_{estimate} , which is calculated from the deposit area on the filter paper, VMD of the basic formulation is also obtained from the CDF curve. With the assumption that the basic formulation has similar droplet size distribution as water, by matching the VMD of the basic formulation to VMD of water, a size factor $f = \text{VMD}_{\text{basic}}/\text{VMD}_{\text{water}}$ is generated. Given a droplet deposit area A from the filter paper, the actual droplet diameter $d = f \cdot (4A/\pi)^{1/2}$, the droplet volume $V = \pi \cdot d^3/6$.

40 The cumulative distributions of droplet volume V of different formulations are plotted with bins of logarithmic scale. From each cumulative distribution curve, the percentage of droplets that have diameters less than 150 μm is counted. This volume percentage of fine droplets corresponds to the degree of drift potential. Using the percentage of a basic formulation (p_{basic}) as a reference, the relative difference of the percentage between a formulation with adjuvants (p) and the basic formulation is computed. The relative difference $r = p/p_{\text{basic}} \cdot 100\%$. If the relative difference (r) is lower than 100%, 45 the formulation has lower potential for drift compared with a basic formulation, and vice versa.

Method 6: Persistent Foam

The persistent foam was determined according to CIPAC Method MT 47.1 with the conditions of using the recipe dose rate and spray volumes indicated in each example and the foam recorded after 1 minute and 3 minutes (www.cipac.org).

5 The method of preparation used was according to Method 1.

10 The adjuvant recipes 1.1, 1.2 and 1.3 were tested with the following commercial products. Rudis® SC and Proline® SC are produced by Bayer AG and contains 480 g/l of prothioconazole for the control of fungal disease. Nativo® WG is produced by Bayer AG and contains 500 g/kg of tebuconazole and 250 g/kg of trifloxystrobin for the control of fungal disease.

15 The products Rudis® SC and Nativo® WG were dispersed in water at the rates in l/ha or kg/ha and in spray volumes l/ha as indicated. To a second dilution of Rudis® SC and Nativo® WG the adjuvant recipes 1.1, 1.2 and 1.3 according to the invention were added at a rate of 0.1 l/ha and the dilution used for the tests below. For greenhouse biological trials it is often necessary to use lower rates than in the field owing to differences in the performance between the greenhouse and the field. This practice is commonly known in the industry.

The results show that Rudis® SC plus recipe 1.1 illustrative of the invention shows higher efficacy than Rudis® SC alone at 15 l/ha and 200 l/ha spray volume.

5 Table 1.3: Biological efficacy of Nativo WG on PUCCRT / wheat.

15	0.025	6.25	12.5	0	100

Method 2: wheat, 3 day curative, evaluation 7 dat. * test error.

The results show that Nativo® WG plus recipe 1.1 illustrative of the invention shows higher efficacy than Nativo® WG alone at 15 l/ha and 200 l/ha spray volume. Furthermore, the high difference at 15 l/ha is surprising.

10 Images of the leaf deposits on sprayed wheat plants are shown in Figure 1 and show that both Rudis SC and Rudis SC + recipe 1.1 illustrative of the invention show poor coverage at 15 l/ha as expected for a spray applied at a low spray volume. The spreading on wheat plants is shown in Table 1.4 and Table 1.5, and it is surprising how Rudis SC + recipe 1.1 and Nativo WG + recipe 1.1 both illustrative of the invention shows higher biological efficacy illustrating that the uptake of the active ingredient by the

15 uptake enhancing agent at low spray volumes has a surprisingly good biological effect.

Leaf wash-off

The wash-off was determined according to method 3.

20 Table 1.4: Leaf wash-off data.

Recipe	Amount of deposit remaining after 1h on corn leaves	Amount of deposit remaining after 1h on apple leaves
Nativo WG – 15 l/ha	++	++
Nativo WG – 200 l/ha	+++	++++
Nativo WG + Recipe 1.1 according to the invention – 15 l/ha	+++++	+++++
Nativo WG + Recipe 1.2 according to the invention – 15 l/ha	+++++	+++++
Nativo WG + Recipe 1.1 according to the invention – 200 l/ha	+++++	+++++
Nativo WG + Recipe 1.2 according to the invention – 200 l/ha	+++++	+++++

Nativo WG was used at a rate of 0.16 kg/ha and recipes 1.1 and 1.2 at a rate of 0.1 l/ha.

The results show that the addition of recipes 1.1 and 1.2 according to the invention reduced the amount of wash-off from Nativo WG. Furthermore, the effect is greatest at the low spray volume of 15 l/ha.

5 Drift

The drift was determined according to method 5.

Table 1.5: Drift data.

Spray volume	Amount of driftable spray droplets (at %vol < 100 microns) from Rudis SC + recipe 1.1 according to the invention compared to Rudis SC + recipe 1.3 not according to the invention %
15 l/ha	74.3

Rudis SC was used at a rate of 0.104 l/ha and recipes 1.1 and 1.3 at a rate of 0.1 l/ha.

10 The results show that recipe 1.1 according to the invention containing methylated rape seed oil (b) shows a lower amount of driftable spray droplets less than 100 microns than the reference recipe 1.3 without added oil.

5 The adjuvant recipe 2.1 was tested with Nativo® WG as in Example 1. Nativo® WG was dispersed in water at the rate kg/ha and in spray volumes l/ha as indicated. To a second dilution of Nativo® WG the adjuvant recipe 2.1 according to the invention was added at a rate of 0.1 l/ha and the dilution used for the tests below.
