SYNTHESIS OF TAXOL™ AND ITS DERIVATIVES

This invention was made with Government support awarded by the National Institutes of Health. The United States Government has certain rights in the invention.

BACKGROUND OF THE INVENTION

The present invention is directed to a process for the synthesis of taxol™ and other tricyclic and tetracyclic taxanes and novel intermediates thereof.

The taxane family of terpenes, of which taxol™ is a member, has attracted considerable interest in both the biological and chemical arts. Taxol™ is a promising cancer chemotherapeutic agent with a broad spectrum of antileukemic and tumor-inhibiting activity. Taxol™ has the following structure:

wherein Ac is acetyl.

The supply of taxol is presently being provided by the bark from Taxus brevifolia (Western Yew). However, taxol™ is found only in minute quantities in the bark of these slow growing evergreens. Consequently, chemists in recent years have expended their energies in trying to find a viable synthetic route for the preparation of taxol™. To date, the results have not been entirely satisfactory.

64725-665

2

A semi-synthetic approach to the preparation of taxolTM has been described by Greene, et al. in JACS 110, 5917 (1988), and involves the use of a congener of taxolTM, 10-deacetyl baccatin III which has the structure of formula II shown below:

10-deacetyl baccatin III is more readily available than taxolTM since it can be obtained from the needles of Taxus baccata. According to the method of Greene et al., 10-deacetyl baccatin III ("10-DAB") is converted to taxolTM by attachment of the C-10 acetyl group and by attachment of the C-13 β -amido ester side chain through the esterification of the C-13 alcohol with a β -amido carboxylic acid unit.

Denis et al. in U.S. Patent No. 4,924,011 disclose another process for preparing derivatives of baccatin III or of 10-deacetylbaccatin III of general formula

(VII)

in which R₂ is an acetyl hydroxy-protecting group and R₃ is a hydroxy-protecting group, and the protecting groups R₁, R₂ and, where appropriate, R₃ are then replaced by hydrogen.

Other semisynthetic approaches for the preparation of taxolTM and for the preparation of other taxanes which possess tumor-inhibiting properties have been reported in recent years, but each of these approaches requires 10-DAB or baccatin III as a starting material. As such, the supply of taxolTM and other taxane derivatives remains dependent at least to some extent upon the collection of various parts of plants from the

remote corners of the world and the extraction of 10-DAB and/or baccatin III therefrom.

SUMMARY OF THE INVENTION

Among the objects of the present invention, therefore, is the provision of a process for the synthesis of taxol[™] and other tetracyclic taxanes; the provision of such a process which is highly diastereoselective; the provision of such a process which proceeds in relatively high yield; and the provision of key intermediates and processes for their preparation.

5 An exemplary synthesis of baccatin III or 10-DAB is depicted hereinbelow in Reaction Scheme A. The starting material, diol **2**, can be prepared from patchino (commonly known as B-patchouline epoxide) which is commercially available. The patchino is first reacted with an organo-metallic, such as lithium t-butyl followed by oxidation with an organic peroxide, such as t-butylperoxide in the presence of titanium
10 tetraisopropoxide to form a tertiary alcohol. The tertiary alcohol is then reacted with a Lewis acid, such as boron trifluoride at low temperature, in the range from 40°C to -100°C; in the presence of an acid, such as
15 trifluoromethane sulfonic acid. A graphical depiction of this reaction scheme along with an experimental write-up for the preparation of diol **2** can be found in U.S. Patent No. 4,876,399.

In Reaction Scheme A, P_5 is TMS, P_7 is MOP or BOM, P_{10} is TES, P_{13} is TBS, and R is ethyl in compounds 6 and 7, methyl in compounds 15, 16, and 17, Ms in compounds 24aa and 26a, and Ts in compound 26aa. It should be understood, however, that P_5 , P_7 , P_{10} , and P_{13} may be other hydroxy protecting groups and R may comprise other lower alkyl substituents in compounds 6, 7, 15, 16 and 17.

Reaction Scheme A may be varied between compounds 18 and 29 as set forth below in Reaction Scheme A', with the reactions leading to compound 18 and following compound 29 being as set forth in Reaction Scheme A.

Reaction Scheme A'

33

In Reaction Scheme A', P_5 is TMS or Ac, P_7 is MOP or BOM, P_{10} is TES, P_{13} is TBS and P_{520} is acetal or ketal, preferably acetonide. It should be understood, however, that P_5 , P_7 , P_{10} , and P_{13} and P_{520} may be other hydroxy protecting groups.

In general, tricyclic and tetracyclic taxanes bearing C13 side chains may be obtained by reacting a β -lactam with alkoxides having the taxane tricyclic or tetracyclic nucleus and a C-13 metallic oxide substituent to form compounds having a β -amido ester substituent at C-13. The β -lactams have the following structural formula:

35

wherein $X_1 - X_5$ are as defined above. The alkoxides having the tricyclic or tetracyclic taxane nucleus and a C-13 metallic oxide or ammonium oxide substituent have the following structural formula:

wherein $R_1, R_2, R_{4a}, R_{4b}, R_5, R_6, R_{6a}, R_{7a}, R_9$, and R_{10} are as previously defined, R_{13} is $-OM$ and M comprises ammonium or is a metal optionally selected from Group IA, IIA, transition (including lanthanides and actinides), IIB, IIIA IVA, VA, or VIA metals (CAS version). If M comprises ammonium, it is preferably tetraalkylammonium and the alkyl component of the tetraalkylammonium substituent is preferably $C_1 - C_{10}$ alkyl such as methyl or butyl. Most preferably, the alkoxide has the tetracyclic taxane nucleus and corresponds to the structural formula:

wherein M, R₂, R_{4a}, R_{7a}, R₉, and R₁₀ are as previously defined.

As set forth in Reaction Scheme A, taxol may be prepared by converting 7-protected Baccatin III **35** to the corresponding alkoxide and reacting the alkoxide with a β -lactam in which X₁ is protected hydroxy, X₃ is phenyl and X₅ is benzoyl. Protecting groups such as 2-methoxypropyl ("MOP"), 1-ethoxyethyl ("EE") are preferred, but a variety of other standard protecting groups such as the triethylsilyl group or other trialkyl (or aryl) silyl groups may be used. Taxanes having alternative side chain substituents may be prepared through the use of β -lactams which comprise the alternative substituents.

Taxanes having alternative C9 substituents may be prepared by selectively reducing the C9 keto substituent of taxol, 10-DAB, Baccatin III or one of the other intermediates disclosed herein to yield the corresponding C9 β -hydroxy derivative. The reducing agent is preferably a borohydride and, most preferably, tetrabutylammoniumborohydride (Bu₄NBH₄) or triacetoxyborohydride.

As illustrated in Reaction Scheme 1, the reaction of baccatin III with Bu₄NBH₄ in methylene chloride yields 9-desoxo-9 β -hydroxybaccatin III **5**. After the C7 hydroxy group is protected with the triethylsilyl protecting group, for example, a suitable side chain may

be attached to 7-protected-9 β -hydroxy derivative **6** as elsewhere described herein. Removal of the remaining protecting groups thus yields 9 β -hydroxy-desoxo taxol or other 9 β -hydroxytetracyclic taxane having a C13 side chain.

REACTION SCHEME 1

Alternatively, the C13 hydroxy group of 7-protected-9 β -hydroxy derivative **6** may be protected with trimethylsilyl or other protecting group which can be selectively removed relative to the C7 hydroxy protecting group as illustrated in Reaction Scheme 2, to enable further selective manipulation of the various substituents of the taxane. For example, reaction of

7,13-protected-9 β -hydroxy derivative **7** with KH causes the acetate group to migrate from C10 to C9 and the hydroxy group to migrate from C9 to C10, thereby yielding 10-desacetyl derivative **8**. Protection of the C10 hydroxy group of 10-desacetyl derivative **8** with triethylsilyl yields derivative **9**. Selective removal of the C13 hydroxy protecting group from derivative **9** yields derivative **10** to which a suitable side chain may be attached as described above.

REACTION SCHEME 2

As shown in Reaction Scheme 3, 10-oxo derivative **11** can be provided by oxidation of 10-desacetyl derivative **8**. Thereafter, the C13 hydroxy

protecting group can be selectively removed followed by attachment of a side chain as described above to yield 9-acetoxy-10-oxo-taxol or other 9-acetoxy-10-oxotetracyclic taxanes having a C13 side chain. Alternatively, the C9 acetate group can be selectively removed by reduction of 10-oxo derivative **11** with a reducing agent such as samarium diiodide to yield 9-desoxo-10-oxo derivative **12** from which the C13 hydroxy protecting group can be selectively removed followed by attachment of a side chain as described above to yield 9-desoxo-10-oxo-taxol or other 9-desoxo-10-oxotetracyclic taxanes having a C13 side chain.

REACTION SCHEME 3

Reaction Scheme 4 illustrates a reaction in which 10-DAB is reduced to yield pentaol **13**. The C7 and

C10 hydroxyl groups of pentaol **13** can then be selectively protected with the triethylsilyl or another protecting group to produce triol **14** to which a C13 side chain can be attached as described above or, alternatively, after further modification of the tetracyclic substituents.

REACTION SCHEME 4

Taxanes having C9 and/or C10 acyloxy substituents other than acetate can be prepared using 10-DAB as a starting material as illustrated in Reaction Scheme 5. Reaction of 10-DAB with triethylsilyl chloride in pyridine yields 7-protected 10-DAB **15**. The C10 hydroxy substituent of 7-protected 10-DAB **15** may then be readily acylated with any standard acylating agent to

42

yield derivative **16** having a new C10 acyloxy substituent. Selective reduction of the C9 keto substituent of derivative **16** yields 9 β -hydroxy derivative **17** to which a C13 side chain may be attached. Alternatively, the C10 and C9 groups can be caused to migrate as set forth in Reaction Scheme 2, above.

REACTION SCHEME 5

Taxanes having alternative C2 and/or C4 esters can be prepared using baccatin III and 10-DAB as starting materials. The C2 and/or C4 esters of baccatin III and 10-DAB can be selectively reduced to the corresponding alcohol(s) using reducing agents such as LAH or Red-Al, and new esters can thereafter be substituted using

standard acylating agents such as anhydrides and acid chlorides in combination with an amine such as pyridine, triethylamine, DMAP, or diisopropyl ethyl amine. Alternatively, the C2 and/or C4 alcohols may be converted to new C2 and/or C4 esters through formation of the corresponding alkoxide by treatment of the alcohol with a suitable base such as LDA followed by an acylating agent such as an acid chloride.

Baccatin III and 10-DAB analogs having different substituents at C2 and/or C4 can be prepared as set forth in Reaction Schemes 6-10. To simplify the description, 10-DAB is used as the starting material. It should be understood, however, that baccatin III derivatives or analogs may be produced using the same series of reactions (except for the protection of the C10 hydroxy group) by simply replacing 10-DAB with baccatin III as the starting material. 9-desoxo derivatives of the baccatin III and 10-DAB analogs having different substituents at C2 and/or C4 can then be prepared by reducing the C9 keto substituent of these analogs and carrying out the other reactions described above.

In Reaction Scheme 6, protected 10-DAB **3** is converted to the triol **18** with lithium aluminum hydride. Triol **18** is then converted to the corresponding C4 ester using Cl_2CO in pyridine followed by a nucleophilic agent (e.g., Grignard reagents or alkyllithium reagents).

Scheme 6

5 Deprotonation of triol **18** with LDA followed by introduction of an acid chloride selectively gives the C4 ester. For example, when acetyl chloride was used, triol **18** was converted to 1,2 diol **4** as set forth in Reaction Scheme 7.

10 Triol **18** can also readily be converted to the 1,2 carbonate **19**. Acetylation of carbonate **19** under vigorous standard conditions provides carbonate **21** as described in Reaction Scheme 8; addition of alkyllithiums or Grignard reagents to carbonate **19** provides the C2

45

ester having a free hydroxyl group at C4 as set forth in Reaction Scheme 6.

Scheme 7

5

Scheme 8

As set forth in Reaction Scheme 9, other C4 substituents can be provided by reacting carbonate **19** with an acid chloride and a tertiary amine to yield carbonate **22** which is then reacted with alkylolithiums or Grignard reagents to provide 10-DAB derivatives having new substituents at C2.

Scheme 9

Alternatively, baccatin III may be used as a starting material and reacted as shown in Reaction Scheme 10. After being protected at C7 and C13, baccatin III is reduced with LAH to produce 1,2,4,10 tetraol **24**. Tetraol **24** is converted to carbonate **25** using Cl_2CO and pyridine, and carbonate **25** is acylated at C10 with an acid chloride

and pyridine to produce carbonate **26** (as shown) or with acetic anhydride and pyridine (not shown). Acetylation of carbonate **26** under vigorous standard conditions provides carbonate **27** which is then reacted with alkyl
5 lithiums to provide the baccatin III derivatives having new substituents at C2 and C10.

Scheme 10

48

10-desacetoxy derivatives of baccatin III and 10-desoxy derivatives of 10-DAB may be prepared by reacting baccatin III or 10-DAB (or their derivatives) with samarium diiodide. Reaction between the tetracyclic taxane having a C10 leaving group and samarium diiodide may be carried out at 0°C in a solvent such as tetrahydrofuran. Advantageously, the samarium diiodide selectively abstracts the C10 leaving group; C13 side chains and other substituents on the tetracyclic nucleus remain undisturbed. Thereafter, the C9 keto substituent may be reduced to provide the corresponding 9-desoxo-9β-hydroxy-10-desacetoxy or 10-desoxy derivatives as otherwise described herein.

C7 dihydro and other C7 substituted taxanes can be prepared as set forth in Reaction Schemes 11, 12 and 12a.

REACTION SCHEME 11

50

REACTION SCHEME 12

51

REACTION SCHEME 12a

As shown in Reaction Scheme 12, Baccatin III may be converted into 7-fluoro baccatin III by treatment with FAR at room temperature in THF solution. Other baccatin derivatives with a free C7 hydroxyl group behave similarly. Alternatively, 7-chloro baccatin III can be prepared by treatment of baccatin III with methane sulfonyl chloride and triethylamine in methylene chloride solution containing an excess of triethylamine hydrochloride.

Taxanes having C7 acyloxy substituents can be prepared as set forth in Reaction Scheme 12a, 7,13-protected 10-oxo-derivative 11 is converted to its corresponding C13 alkoxide by selectively removing the C13 protecting group and replacing it with a metal such as lithium. The alkoxide is then reacted with a β -lactam or other side chain precursor. Subsequent hydrolysis of the C7 protecting groups causes a migration of the C7 hydroxy substituent to C10, migration of the C10 oxo substituent to C9, and migration of the C9 acyloxy substituent to C7.

As shown in Reaction Scheme 13, 7-O-triethylsilyl baccatin III can be converted to a tricyclic taxane through the action of trimethyloxonium tetrafluoroborate in methylene chloride solution. The product diol then reacts with lead tetraacetate to provide the corresponding C4 ketone.

REACTION SCHEME 13

The subprocesses of Reaction scheme A can be applied at various stages. For example, the process for the conversion of compound 30 to compound 33 can be applied to any intermediate having a hydroxyl group at C-10 and two hydrogens at C-9, e.g., the process for introducing C9 and C10 carbonyl and hydroxyl groups can be applied to suitably protected intermediates 4 through 29.

Likewise, the process for introduction of C1 and C2 oxygen-containing functional groups (conversion of 6 to 13 in Reaction Scheme A) can be applied to any intermediate having a C3 carbonyl group.

Similarly, the process for introducing C2 and C4 acyl groups as exemplified in Reaction Schemes 6 through 10 can be applied to any intermediate having a C1, C2 carbonate.

5 Also, the process for forming the oxetane ring, as exemplified in the conversion of 24a to 27a in Reaction Scheme A, can be applied to a variety of intermediates having a C4 carbonyl group.

10 The aldol process exemplified in the conversion of 5 to 6 in Reaction Scheme A can be applied to any suitably protected intermediate having a C3 carbonyl group and a C8a hydrogen. A variety of ketones or aldehydes can be used as a reactant in this process.

15 Formation of a cyclic carbonate from any 1,2 or 1,3 diol subunit in any intermediate can be carried out by using phosgene as a reactant. Carbonyl groups can be reduced by hydride reagents or metallic species to the corresponding alcohols. Alcohols can be oxidized using a variety of oxidizing agents as exemplified in the
20 Reaction Schemes, to the corresponding carbonyl groups.

25 The compounds disclosed in this application have several asymmetric carbons and may exist in diastereomeric, racemic, or optically active forms. All of these forms are contemplated within the scope of this invention. More specifically, the present invention includes the enantiomers, diastereomers, racemic mixtures, and other mixtures of the compounds disclosed herein.

After 1.75 h, the reaction mixture was diluted with 150 mL of hexane, then poured into 100 mL of a saturated aqueous NaHCO_3 solution and 150 mL of hexane. The organic phase was washed with two 100 mL portions of saturated aqueous NaHCO_3 solution and with 100 mL of water, dried over anhydrous Na_2SO_4 , and concentrated under reduced pressure to give 4.88 g of crude triethylsilyloxyalcohol 3. An analytical sample was obtained by plug filtration through a short pad of silica gel washing with hexane and then eluting the pure compound 3 (P_{10} = TES) (colorless oil) with 5% ethyl acetate in hexane.

Keto Lactone 11. To the 2-keto-3-hydroxylactone 10 (P_{10} = TES, P_{13} = TBS) (1.10 g, 1.83 mmol) was added a 0.1 M solution of SmI_2 in THF (82 mL, 8.2 mmol). The resulting dark blue solution was stirred at room temperature under N_2 for 4h. After cooling to 0 °C an ethereal solution of HCl (0.66M; 4.2 mL, 2.77 mmol) was added; after 5 min the flask was opened to the air and the reaction mixture was diluted with 200 mL of cold ethyl acetate, then poured into 50 mL of ice cold 0.2N aqueous HCl. The organic phase was separated and washed with 50 mL of a 5% aqueous citric acid solution, two 50 mL portions of a saturated aqueous NaHCO_3 solution and 50 mL of brine, dried over anhydrous Na_2SO_4 and concentrated under reduced pressure. The resulting material was dissolved in 100 mL of hexanes, then silica gel (230-400 mesh; 4.3 g) was added and the mixture was vigorously stirred at room temperature for 65 min before filtering through a 1 inch pad of silica gel eluting with 300 mL of 20% ethyl acetate in hexanes. The solvent was evaporated under reduced pressure and the residue was purified by silica gel chromatography, eluting with 10% ethyl acetate in hexanes to yield 822 mg (77%) of the *cis*-ketolactone 11 and 164 mg (15%) of the corresponding *trans* isomer.

To a solution of the *trans*-2-ketolactone (611 mg, 1.03 mmol) stirred in 10 mL of THF under nitrogen at 0 °C was added down the side of the flask 6.8 mL of a 0.6 M solution (4.1 mmol) of *t*-BuOK in THF. The resulting solution was stirred for 1.5 h then 10 mL of a 10% acetic acid solution in THF was added down the side of the flask. After stirring for 5 min the mixture was diluted with 200 mL of hexanes and poured into 100 mL of a saturated aqueous NaHCO_3 solution. The organic layer was washed with water and brine then dried over anhydrous Na_2SO_4 and concentrated under reduced pressure to yield 615 mg of pale brown oil. The oil was dissolved in 10 mL of hexanes and silica gel (3.0 g) was added. The mixture was stirred vigorously for 15 min then filtered through a 1/2 in plug of silica gel with 20% ethyl acetate in hexanes. Concentration of the filtrate under reduced pressure yielded 576 mg of pale yellow oil. This material was purified by silica gel chromatography, eluting with 10% then 20% ethyl acetate in hexanes to yield 472 mg (77%) of pure *cis*-2-ketolactone 11 (P_{10} = TES, P_{13} = TBS), 84 mg (13%) of pure *trans* isomer and 24 mg of a 6:1 mixture of *cis:trans* isomers.

To a stirred solution of oxetane 29 (P_7 = BOM, P_{10} = TES, P_{13} = TBS) (16 mg, 0.02 mmole) in acetonitrile (0.33 mL) at 0 °C was added a 4% solution of HF-pyridine complex in acetonitrile (0.8 mL). The solution was stirred at 0 °C for 11 h, diluted with ethyl acetate, poured into 20 mL of a saturated aqueous NaHCO_3 solution and extracted with CHCl_3 (30 mL x 3). The combined organic phases were dried over anhydrous Na_2SO_4 and concentrated under reduced pressure to give 13.5 mg (0.0196 mmole) of 30a as an oil. This oil was dissolved in THF (1 mL) and cooled to -78 °C. To this solution at -78 °C was added a 0.285 M solution of phenyllithium in THF (0.144 mL, 2.1 eq.). After 10 min, the solution was poured into 20 mL of saturated aqueous NaHCO_3 solution and CHCl_3 (30 mL x 3). The combined organic phase was dried over anhydrous Na_2SO_4 and concentrated under reduced pressure to give 16 mg of a pale yellow oil, which was crystalized to yield 12.7 mg (85%) of benzoate 31 (P_7 = BOM, P_{13} = TBS, R = H).

Ketone 32. To a solution of benzoate 31 (P_7 = BOM, P_{13} = TBS, R = H) (18 mg, 0.235 mmole) and 4-methylmorpholine N-oxide (18 mg, 0.154 mmole) in CH_2Cl_2 (2.6 mL) at room temperature was added tetrapropylammonium perruthenate (6 mg, 0.017 mmole). The solution was stirred at room temperature for 15 min and filtered through silica gel with 30 % ethyl acetate/hexane. The filtrate was concentrated under reduced pressure to yield ketobenzoate 32 (P_7 = BOM, P_{13} = TBS) (18 mg, 100%).

7-BOM-Taxol. To a solution of 7-BOM baccatin III (35) (13.2 mg, 0.018 mmol) in 0.25 mL of THF at -45 °C was added dropwise 21 μ L of a 1.03 M solution of lithium bis(trimethylsilyl)amide in THF. After 1h at -45 °C, a solution of (S)-cis-1-benzoyl-3-triethylsilyloxy-4-azetidin-2-one (15

mg, 0.039 mmol) in 0.25 mL of THF was added dropwise to the mixture. The solution was warmed to 0 °C and kept at that temperature for 1 h before 0.2 mL of a 10% solution of AcOH in THF was added. The mixture was partitioned between saturated aqueous NaHCO₃ and 60% ethyl acetate / hexane. Evaporation of the organic layer gave a residue which was purified by filtration through silica gel to give 20.2 mg of crude (2'R,3'S)-2'-triethylsilyl-7-BOM taxol.

To a solution of 20.2 mg (0.018 mmol) of (2'R,3'S)-2'-triethylsilyl-7-BOM taxol in 0.8 mL of acetonitrile and 0.3 mL of pyridine at 0 °C was added 0.10 mL of 48% aqueous HF. To a stirred solution of this material (1 mg) and dimethyl aminopyridine (1.5 mg) in pyridine (10 μ L) under nitrogen at room temperature was added acetic anhydride (5 μ L). The solution was stirred for 15 h, diluted with ethyl acetate, poured into 20 mL of a 10% aqueous CuSO₄ solution and extracted with ethyl acetate (20 mL x 3). The combined organic phase was washed with a saturated aqueous NaHCO₃ solution, dried over anhydrous Na₂SO₄ and concentrated under reduced pressure to give 2 mg of a pale yellow oil. The oil was column chromatographed (25% ethyl acetate/hexane) to yield 0.6 mg of oxetane 29.
