Tractor-Trailer brake control system.

A tractor (28)-semi-trailer (30) brake system control for distributing brake effort to obtain inter-tractor-trailer balanced and proportional braking, depending upon the magnitude of operator demand for braking effort, is provided. The control utilizes sensors (80, 170, 172) provided solely on the tractor.
TRACTOR TRAILER BRAKE CONTROL SYSTEM

CROSS REFERENCE TO RELATED APPLICATION

This application is a continuation-in-part of U.S. Patent application Serial No. 043,010, filed April 27, 1987.

BACKGROUND OF THE INVENTION

Field of the Invention

This invention relates to controls for brake systems for multiple vehicle systems (i.e. tractor-trailer vehicles). In particular, this invention relates to controls for tractor-trailer brake systems which, depending upon the level of operator demand for braking, will distribute the braking effort between the individually controllable vehicle brake sites, such as between sub-vehicle brake systems, to achieve inter-vehicle balanced braking or proportional braking or a compromise thereof.

Description of the Prior Art

Brake systems, and the controls therefor, for vehicles, including heavy duty vehicles such as trucks, are, of course, well known in the prior art.

Brake systems for passenger cars are, in general, somewhat easier to design than brake systems for heavy duty vehicles such as tractor-trailer trucks as the loading of passenger vehicles will not vary to the extent loading will vary on a tractor only, a tractor with an empty or lightly loaded trailer or a tractor with a heavily loaded trailer.

Brake systems of the anti-lock type, for all types of vehicles, are well known in the prior art. Briefly, these systems operate to obtain a maximized vehicle stability (i.e. maximized transverse coefficient of friction of braked wheels) by maintaining the longitudinal slip of the braked wheels within predetermined limits. This usually requires modulating the braking forces on an individual wheel and/or individual axle basis to maintain at least some wheel rotation.

Examples of prior art anti-lock systems may be seen by reference to United States Patent Nos. 3,767,270; 3,768,872; 3,854,556; 3,893,696; 3,929,383; 3,929,382; 3,966,267; 4,392,202 and 4,591,213, the disclosures of all of which are hereby incorporated by reference.

Brake systems which control braking to achieve a driver demand, sense driver demand in a "brake-by-wire" manner, sense coefficient of friction and modify brake forces accordingly, sense load on a wheel and modify braking effort accordingly, sense wheel slip and/or use electronic signals to achieve more rapid trailer brake response are also disclosed in the prior art as may be seen by reference to United States Patent Nos. 4,140,352; 4,327,414; 4,494,199; 4,512,615; 4,545,240; 4,591,213; 4,606,588; 4,616,881; and 4,648,663, the disclosures of all which are hereby incorporated by reference.

While the prior art brake systems which modify braking effort in response to sensed parameters to achieve various goals, such as vehicle stability or the like, do, in general, provide enhanced vehicle braking, they are subject to further improvement as both inter-vehicle balanced and inter-vehicle proportional braking, depending upon operator demand, is not provided.

SUMMARY OF THE INVENTION

In accordance with the present invention, many of the drawbacks of the prior art have been overcome or minimized by the provision of a multiple mode vehicle brake control system particularly well suited for heavy duty articulated multiple vehicle systems such as tractor-trailers.

The above is accomplished by providing a brake control system having means to sense the magnitude of the brake effort required by the operator (usually sensed as a percentage of displacement of the vehicle
brake pedal), means mounted on the tractor to sense vehicle system parameters and means to distribute the braking effort between the braked wheels, or sets of braked wheels, to achieve balanced braking under conditions of relatively low operator demand and proportioned braking under conditions of relatively high operator demand.

Accordingly, it is an object of the present invention to provide an improved tractor-trailer braking system control for distributing the braking effort between the individually controllable brake wheels, or sets of wheels, to achieve inter-vehicle balanced and proportional braking.

This and other objectives and advantages of the present invention will become apparent from a reading of the detailed disclosure of the preferred embodiments taken in connection with the drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 is a chart illustrating the multiple modes of the vehicle braking provided by the present invention.

Figure 2 is a schematic illustration of a single vehicle system.

Figure 3 is a schematic illustration of a multiple vehicle system in which the brake control system of the present invention may be utilized.

Figure 4 is a schematic illustration of a prior art load sensor which may be utilized with the brake system of the present invention.

Figure 5 is a schematic illustration of the brake system of the present invention for the single vehicle system illustrated in Figure 2.

Figure 6 is a schematic illustration of the brake system of the present invention for the multiple vehicle system of Figure 3.

Figure 7 is a schematic illustration of a standard trailer brake system which may be utilized with the brake system of Figure 6.

Figure 8 is a schematic illustration of the method for determining the type and number of trailer brakes.

Figure 10 is an equilibrium force diagram for the multiple vehicle system of Figure 3.

DESCRIPTION OF THE PREFERRED EMBODIMENT

The various modes of operation for a vehicle brake system according to the present invention are illustrated in chart 10 of Figure 1. Briefly, as illustrated in section 12, at relatively low demands for brake effort (sensed by force applied to and/or displacement of the vehicle brake pedal) the system will minimize wear on the brake friction surfaces by controlling the brakes to balance braking effort. As illustrated in section 14, at relatively high demands for brake effort, the system will distribute the braking effort in proportion to load to maximize vehicle braking capability and stability. At intermediate demands for braking effort, section 16, the braking effort is distributed in a manner to achieve a smooth transition from balanced to proportional distribution of the braking effort.

Preferably, the system will, as shown in section 18, have an anti-lock mode wherein, if actual or impending wheel-lock is sensed at any one or more wheels, the brakes will be applied and released (usually with a proportioned distribution of braking effort) to keep the wheels turning to utilize the higher sideways adhesion of non-locked wheels.

Additionally, if the vehicle is equipped with driveline and/or engine retarder means, the system may utilize such retarders at lower brake effort demand, as shown in section 20, as a substitute for, or supplement to, the vehicle brakes to minimize vehicle operating costs.

The vehicle brake control system of the present invention is effective to distribute the braking effort between the individually controlled braked wheels or sets of wheels of the vehicle in multiple modes as a function of the magnitude of operator demand for braking effort.

One of the modes, herein defined as the "proportional braking" mode, is well known in the vehicle industry and involves the "braking ratio", which is the ratio of tangential friction force to radial load (i.e. $F_p/F_r$ in Figure 9) for the tire/road interface.

The limiting value, of course, is the coefficient of friction ("MU"). If each wheel or set of wheels develops tangential friction force (or braking force) to load in the same proportion, or ratio, then, to the extent each of the wheels have equal MU to slip relationships, the vehicle can utilize all of the available
adhesion on all of its wheels at the same time. This principal and the advantageous effects of achieving equal braking ratios at each wheel is well known in the braking industry.

Specifically, proportional braking, as used herein means a braking effort distribution on a vehicle where the ratio of tangential braking force to radial load force is (or very nearly is) the same for all wheels or sets of wheels or is related in a predetermined manner. The wheels may be considered individually or taken in sets, the sets may consist of all of the wheels on one axle, all of the wheels on a tandem pair of axles (a bogey set), or all the wheels on one sub-vehicle when the vehicle is the combined total of several sub-vehicles.

Another, different, principal for the distribution of braking effort in a vehicle braking system is to create braking energy inputs related to some brake or vehicle system parameter other than the loads or tire to road adhesion factors. Some of these parameters are: balanced wear, or balanced work, or balanced temperature between brakes. Whatever the parameter chosen, the distribution of braking effort to balance it is, in general, different from the distribution of braking effort in proportional braking.

Balanced braking as used herein is a braking effort distribution on a vehicle wherein the distribution of the braking effort is not dependent upon the radial load forces and which will achieve desired balance, such as equal wear, brake force, temperature, or a parameter directly related to brake wear. The rate of wear of modern brakes is primarily related to the amount of work performed by the brakes (i.e. brake torque times revolutions) factored by the brake temperature, especially the surface temperature of the linings. The temperature factor in wear is especially severe. For example, wear rates of brake linings at 800°F are as much as four times higher than the wear rates at 300°F. For similarly sized and configured brakes, having similar heat dissipation properties, the brake that does the most work will have the highest temperature and will wear at a rate that is even more exaggerated than the difference in work.

For a given amount of total brake linings in a vehicle brake system, the total lining will provide the longest wear life if all of the lining operates at the lowest possible temperature. That occurs when the heat (energy) is spread uniformly over the drum or disc surface areas. It should also be noted that operation at the lowest possible temperature also tends to provide the largest energy absorption reserve capacity. High energy at one brake will eventually cause it to fail catastrophically although fade is to some extent a self-protecting feature. Accordingly, brake temperature or some other measure of brake energy, including the braking force, can be used to distribute braking effort to balance wear in a vehicle braking system.

A variety of studies of vehicle brake usage, especially brake usage for heavy duty vehicles, indicates that most brake applications are at low demand. For example, on vehicles equipped with an air actuated brake system having capacity for 100 psi brake pressures, ninety percent (90%) of all applications are at less than 20 psi. The majority of brake wear occurs at relatively low brake torque demand by the driver. For the majority of stops, the adhesion capacity of the tire to the road is not approached. A 20 psi brake application on a fully loaded truck axle usually requires no more than a 0.1 friction coefficient. Dry roads can provide 0.6 to 1.0 friction coefficient while wet asphalt can provide 0.3 coefficient of friction. Therefore, brake effort distributions that are based on the extremes of braking capacity, regardless of the magnitude of the operator, do not address some of the needs of the vehicle owner and/or operator.

Inter tractor-trailer balanced braking is a braking effort distribution wherein the average value of a selected parameter to be balanced for each individually controllable tractor brake is the same (or related in a known manner) as the average calculated or sensed value for that parameter for the trailer brakes.

The brake control system of the present invention is intended for multiple vehicle systems such as the tractor-trailer system illustrated in Figure 3. System 24 comprises a tractor 28 and a semi-trailer 30 attached thereto by a connecting means 32 which comprises the well known fifth wheel 34 fixed to the tractor for selective engagement with a king pin fixed to the trailer. The tractor typically comprises a pair or tandem set of rear drive axles 36, 38 and a front steer axle 40. The trailer 30 typically comprises a tandem set or pair of non-steerable non-driven trailer axles 42 and 44. Typically, but not necessarily, the front axles, 27 and 40, are non-driven steerable wheels. As is known, tractor 28 is occasionally driven without a trailer attached thereto (i.e. "bob-tailed").

The braking system of the present invention, as it relates to a multiple vehicle system such as semi-truck tractor trailer system 24, involves at least the inter-vehicle braking effort distribution between tractor 28 and trailer 30, and may also involve the intra-vehicle braking effort distribution for tractor 28 and the intra-vehicle braking effort distribution for trailer 30.

Providing a braking system control, preferably a computer controlled braking system, that can alter braking effort distribution based upon the current state of the vehicle, the environment and the desired output is advantageous. At times, when adhesion is generally not critical, the braking effort distribution goal can be established on some other important factors, equalized wear for instance. At other times, such as when the driver demands higher levels of braking, the system goals can change, for instance to real time
load proportioning. At other times, when demand is at an intermediate level, the goals of the brake
distribution effort can be to blend or transcend balanced and proportional braking without jerking to the
vehicle. Since it is always possible that some of the wheels may have low tire adhesion (i.e. if on a patch of
ice or the like) an anti-lock system could monitor the wheel lockup condition and intercede to reduce the
average braking torque on individual or sets of brakes to retain directional control.

By utilizing an electrically controlled brake system with feedback, optimal response speed and accuracy
of the system is possible. Additionally, the target output is not fixed as with conventional technology, but is
variable depending upon the predetermined logic rules within the central processing unit. The multi-mode
brake effort distribution system of the present invention is an improvement over existing braking systems in
that the system may be controlled to provide an optimal compromise in maintenance cost reduction, brake
reserve capacity maximization and vehicle stopping distance optimization over a variety of vehicle
conditions with high directional stability and steerability. Importantly, these features can be provided for
tractor and trailer combinations, as well as for single vehicle systems, regardless of the condition (within
limits) of the brakes on each of the individual sub-vehicles.

For simplified illustrative purposes, the basic principals of balanced and proportional braking may be
seen by reference to Figure 5 which illustrates a braking system for truck 22. Truck 22 includes a rear drive
axle 26 driven by engine 46 through transmission 48 and drive line 50. A pair of driven wheels 52 and 54 are
associated with the rear drive axle 26 and a pair of front wheels 56 and 58 are associated with the front
steer axle 27. Air actuated brakes 60 and 62 are provided for braking the rotation of wheels 52 and 54,
respectively, and air actuated brakes 64 and 66 are provided for braking the rotational speed of wheels 56
and 58, respectively. Rear brakes 60 and 62 are, as is well known in the prior art, of the same size and type
as likewise are front brakes 64 and 66. In the system illustrated, the brakes are air actuated brakes of one
of the well known types such as the "S" cam actuated drum brake type or the air disc brake type, the
details of which are well known in the prior art and may be seen in greater detail by reference to United
States Patent Nos. 4,476,968 and 4,457,407, the disclosures of both of which are hereby incorporated by
reference. As is known, while both of the front brakes and both of the rear brakes should be of the same
size and type, it is not necessary that the front brakes 64 and 66 be of the same size and/or type as the
rear brakes 60 and 62. Compressed air for actuating the brakes is supplied from a plurality of supply tanks
88, only one of which is shown, from the vehicle compressor (not shown) or the like.

The braking system includes a control unit 70, which for purposes of flexibility and responsiveness is
preferably an electronic microprocessor based control unit having means 72 for receiving a plurality of input
signals, means for processing the input signals in accordance with predetermined logic rules, and means 74
for issuing command output signals to various system operators.

A sensor 76 senses the operator's displacement of a brake pedal 78 to provide an input signal
indicative of the driver's demand for vehicle stopping effort. Sensors of this type are known in the prior art
and may be seen in greater detail by reference to above-mentioned United States Patent Nos. 4,140,352;
4,327,414 and 4,512,615. Typically, such transducers will sense the displacement of and/or force applied to
the brake pedal 78 and will provide an output signal proportional thereto. An input signal indicative of the
deceleration of the vehicle may be provided by means of a decelerometer 80 which is fixed to the vehicle
or by means of a transmission output shaft speed sensor 82 which will provide a signal indicative of the
rotational speed of the drive line which may be differentiated by the CPU 70. Force sensors 82, 84, 86 and
88 are utilized to provide input signals indicative of the braking and load forces at the wheels, 52, 54, 56
and 58, respectively. The force sensors may be strain gauge based and/or of the linearly variable
displacement transducer type as is well known in the prior art. For purposes of achieving a more accurate
distribution of braking effort during the brake balancing mode, temperature sensors 90, 92, 94 and 96 may
be provided for sensing the temperatures of the brakes at wheels 52, 54, 56 and 58 respectively. The
temperature sensors may be non-contact infrared sensors, or the like, as is known in the prior art. To allow
the brake system to have an anti-lock mode, wheel speed sensors 98, 100, 102 and 104 are provided to
provide input signals indicative of the rotational speed of wheels 52, 54, 56 and 58, respectively.

Vehicle acceleration/deceleration can also be measured by use of the wheel speed sensors if proper
allowance is made for slip. Of course, by using the vehicle acceleration/deceleration measurement devices
80 in combination with the wheel speed sensors, a very accurate determination of wheel slip may be
calculated.

The central processing unit 70 will, as will be explained in greater detail below, process the input
signals in accordance with predetermined logic rules to generate command output signals to the control
valves 106 and 108. Briefly, control valve 106 is connected to the supply tank 68 through supply line 110
and will, in accordance with the command output signals from CPU 70, provide pressurized fluid via branch
conduit 112 to brake 60 and branch conduit 114 to brake 62. Control valve 108 is connected to supply line
110 from one of the supply tanks and, in accordance with the command output signals, will provide
independently pressurized air through branch conduit 116 to brake 64 and branch conduit 118 to brake 66.
Accordingly, it may be seen that the braking effort at each of the wheels may be individually controlled in a
closed loop manner in response to command output signals generated by the CPU 70 in response to the
input signals received and processed thereby.

The method of controlling or distributing the braking effort amongst the vehicle wheels 52, 54, 58 and
58 in the brake system for truck 22, will be described in greater detail below. While the braking system of
the present invention involves distribution of the braking effort at each of the wheels, the system measures
and controls the parameter of braking force at each of the wheels as an acceptably accurate indication of
the braking efforts.

In a more simplified and inexpensive alternative system, somewhat less accurate than the preferred
embodiment illustrated in Figure 5, pressure sensors, such as the pressure sensors 120, 124, 126 and 128
may partially replace the force sensors 82, 84, 86 and 88, respectively, as sensors for providing an input
signal indicative of the braking force at the wheels 52, 54, 56 and 58, respectively. Briefly, it has been found
that, given an air actuated brake of known parameters, such as brake size and type, air motor size and
type, lining type, slack adjuster size and type, and the like, the braking force applied by that brake
corresponds in a known manner to the pressure supplied to the air motor with an accuracy of approximately
plus or minus 10%.

While the force sensors 82, 84, 86 and 88 may be of the type providing signals indicative of both
tangential (i.e. braking) force and radial (i.e. load) force, separate load sensors may, in the alternative, be
utilized. Load sensors are well known in the prior art as may be seen by reference to Figure 4, which
illustrates a typical prior art load sensor 130. Such load sensors may be provided for each wheel or may be
provided on an axle-by-axle basis.

In the present example, brake force (F₀ in Figure 9) will be the measured and the controlled parameter
to distribute brake effort or brake work amongst the vehicle wheels. As indicated in Figure 1, when the
operator's demand for braking effort is relatively low (between 0% and A% of 100% demand) the brake
effort will be distributed in a balanced braking mode. When the operator's demand for braking effort is
relatively high (between B% and 100% demand) the brake effort will be distributed in a proportional braking
mode. If operator demand is intermediate (A% to B% of 100% demand) the braking effort will be distributed
in a transitional manner to provide a smooth transition from the balanced to the proportional braking modes.
Typically, A will equal about 15%-30% while B will equal about 30%-40%. Preferably, the values of A and B
will be varied in view of driver requirements, expected duty cycles; fleet maintenance practices and the like.
The values of A and B may also be varied on a closed loop basis in view of sensed vehicle operating
conditions (i.e. high incidence of wheel-lock, etc.).

While, for illustrative purposes, the above example relates to intra-vehicle brake effort distribution
between wheels 52, 54, 56 and 58 of truck 22, the same modes of operation are applicable to the intra-
vehicle distribution of braking effort between the wheels of trailer 30 and to the inter-vehicle distribution of
braking effort between the tractor and trailer of multiple vehicle system 24 (i.e. inter-tractor-trailer balanced
and proportional braking).

During operation in the balanced braking mode, the braking force (BF) at each site of an N site braking
system is:

\[ BF_{XB} = C_{X} \times g(D) \]

where: \( BF_{XB} \) = the braking force at the X site during balanced braking.
\( C_{X} \) = a constant based upon relative brake size, type. \( C_{X} \) is not a function of the load \( V_{X} \) at the X site.
\( g \) = balanced braking function.
\( D \) = sensed demand.

In other words, during balanced braking, the braking force at each wheel (or set of wheels) is a function
(g) of the sensed operator demand (D) times a constant (C) related to known individual brake parameters
(size, type and motor size, etc.)

The CPU 70 will sense the brake force
at each site and will issue command outputs to the control valves 106 and 108 to pressurize brakes 60, 62, 64 and 66 to minimize the error (\(E_{XB}\)) equation:

\[
E_{XB} = BF_{XB} - BFS_X
\]

If \(E_{XB}\) is positive, increased pressure is applied to the brake, if \(E_{XB}\) is negative, the pressure applied to the brake is decreased.

Generally, during balanced braking, the goal is to balance wear. If temperature is not sensed, heat dissipation is considered to be equal in similar brakes, and, as the entire vehicle is at the same velocity, then ignoring small differences in wheel slip, the product of \((BF) \times \text{vehicle velocity} \times \text{time}\) equals brake input energy. To achieve equal energy input, all \(C_X\) should be equal.

If temperature sensors (90, 92, 94 and 96) are utilized, a much more accurate wear balance may be achieved. In such a situation,

\[
BF_{XB} = C_X \times g(D, T_X)
\]

where \(T_X\) = the temperature at site \(X\).

The force at brake \(X\) would be modified in accordance with the temperature sensed at brake \(X\) relative to the temperature at the other (\(N-1\)) brakes. The higher the sensed temperature at the brake, relative to the temperatures of the other brakes, the lower the \(BF_{XB}\). In such a system having temperature sensors, the energy inputs might start equal, but, if temperature differences diverged due to differences in heat dissipation characteristics, the energy distribution would be redirected accordingly.

During operation in the proportional braking mode, the braking forces at each site of an \(N\) site braking system is

\[
BF_{XP} = K_X \times f(D, L_X)
\]

where:
- \(BF_{XP}\) = the braking force at the \(X\) site during proportional braking;
- \(K_X\) = a constant based upon relative brake parameters;
- \(f\) = proportional braking function;
- \(D\) = sensed demand;
- \(L_X\) = load at \(X\) site

In other words, during proportional braking, the braking force at each site is a function \((f)\) of sensed demand \((D)\) and the load \((L)\) at the site. The load may be sensed by force sensors 82, 84, 86 and 88, or separate load sensors, such as sensor 130, may be provided at each of the \(N\) sites.

As with balanced braking, during proportional braking the CPU 70 will sense the brake force at each site \((BFS_x)\) and issue command outputs to the control valves 106 and 108 to minimize the error \((E_{PX})\) equation:

\[
E_{PX} = BF_{XP} - BFS_X
\]

In general, in the proportional braking mode, the brake force to be applied at each site is directly proportional to operator demand multiplied by the product of the mean braking ratio times the sensed load.
For operation in the transitional mode, the braking forces at each site of the n site braking system is

\[ F_{XI} = h \left( C_X, K_X, D, L_X \right) \]

where \( B_{FXI} \) = the braking force at the X site during intermediate braking;
\( h = \) intermediate braking function.

In other words, during intermediate or transitional braking, the braking force at each site is an interpolation of the other modes designed to provide a smooth transition therebetween.

As with the other modes, the CPU will issue commands to the control valves to minimize the error (\( E_{IX} \)) equation at each site.

\[ E_{IX} = B_{FXI} - B_{FSX} \]

As indicated above, a relatively less expensive but somewhat less accurate brake system for truck 22 can be provided by eliminating the horizontal force sensors 82, 84, 86 and 88 associated with wheel 52, 54, 56 and 58, respectively, and replacing same with pressure sensors 120, 124, 128 and 128 and utilizing prior art type vertical load sensors 130 for each wheel. In such a system, pressure applied to each brake is the parameter which is monitored and controlled. It has been observed, that in a brake of known size and type, that the pressure applied to the air motor thereof is a relatively accurate indication of the braking force applied by that brake.

The braking system of the present invention is specifically applicable to multi-vehicle systems such as the tractor 28 and trailer 30 system 24 illustrated in Figure 3. Referring to Figure 6, the braking system for the tractor 28 of multi-vehicle system 24 may be seen. Briefly, as is well known in the prior art, tractor 28 includes a front steer axle 40, which is usually not driven, and a tandem pair of rear drive axles comprising front-rear drive axle 36 and rear-rear drive axle 38. Wheels 140 and 142 are associated with the rear-rear drive axle 38, wheels 144 and 146 are associated with the front-rear drive axle 36 and wheels 148 and 150 are associated with the front steer axle 40. As is typical with tractors, dual tires are utilized with each wheel of the rear drive axles. With the exception of requiring additional sets of rear brakes 152 and 154, load sensors 156 and 158, speed sensors 160 and 162, and temperature sensors 164 and 166, the brake system for tractor 28, as it relates to intra-tractor brake effort distribution is substantially identical in function and structure to the control system for truck 22 illustrated in Figure 5. Accordingly, elements of the brake control system for tractor 28 which correspond with those utilized for truck 22 will be assigned like reference numerals and will not be described again in detail.

Rear control valve 168 is substantially identical to rear control valve 106 illustrated in Figure 5 except that four individually controlled branch lines extend therefrom.

Briefly, air brakes 152 and 154 are substantially identical to air brakes 60 and 62. Force sensors 156 and 158 are preferably strain-gauge based devices and are substantially structurally and functionally identical to force sensors 82 and 84. Wheel speed sensors 160 and 162 are substantially structurally and functionally identical to wheel speed sensors 98 and 100 while temperature sensors 164 and 166 are substantially structurally and functionally identical to temperature sensors 90 and 92.

With the exception that the brake system for tractor 28 includes six rather than four braked wheels (i.e. \( N = 6 \) rather than \( N = 4 \)) as compared to the brake system for truck 22, the intra-tractor balanced, transitional and proportional braking modes are substantially identical to the same modes described above in connection with the braking system for truck 22.

In a tractor-trailer vehicle system such as system 24 illustrated in Figure 3, the inter-vehicle distribution of braking efforts is extremely important. Generally speaking, in order of magnitude of importance to achieve acceptable vehicle brake performance from both the minimized maintenance and maximized braking performance and stability goals, inter-tractor-trailer proportioned and balanced braking is at least as important as intra-tractor proportional and balanced braking and is considered to be more important than intra-trailer proportional and balanced braking. Accordingly, in a braking system for a tractor-trailer, it is important that means be provided to achieve inter-tractor-trailer braking effort distributions as discussed above. Further, it is also important to remember that tractors 28 are often owned by different individuals.
than those that own the trailers 30 and, even within a fleet with commonly owned tractors and trailers, a
typical fleet will have many many more trailers than tractors. Accordingly, it is highly desirable to provide a
braking control system for a tractor-trailer vehicle system which requires little if any special equipment on
the trailer and will provide relatively accurate tractor-trailer proportional braking and some degree of inter-
tractor-trailer balanced braking.

To achieve a tractor-trailer braking system which will provide an acceptable degree of inter-tractor-trailer
proportional and balanced braking, while requiring no additional equipment on the trailer, the tractor of the
present invention is equipped with an accelerometer 80 for providing an input signal to CPU 70 indicative of
the acceleration/deceleration of the vehicle and a pair of load sensors 170 and 172 for providing input
signals to the CPU 70 indicative of the vertical and horizontal forces at the fifth wheel connection 34
between the tractor and trailer. In addition, a control valve 174, controlled by command outputs from CPU
70, will provide pilot or control signals to the standard trailer brake system control valves.

Referring now to Figure 7, a prior art standard trailer brake system is illustrated. Briefly, the trailer
includes a king pin 178 for selective engagement and disengagement to the tractor fifth wheel 34 as is well
known in the prior art. The trailer includes a supply tank 178 connected to the tractor air system by means
of a fluid connection 180. Trailer axles 42 and 44 support trailer wheels 182, 184, 186 and 188, each of
which is provided with an air brake 190, 192, 194 and 196, respectively. Typically, all of the trailer brakes
are controlled at the same pressure by means of a relay valve 198, which has an inlet 200 connected to the
tractor supply tank 178, and a pilot valve portion 202 for receiving a pilot air signal from the tractor air
system by means of connector 204. Connector 204 is designed for connection with connector 206 on the
tractor. Typically, the connectors 204 and 206 and likewise connector 180 and its associated connection
with the vehicle air system (not shown) that form the fluid connection are known as the "glad hand".

As may be seen by reference to Figure 7, the prior art standard trailer 30 has a brake system wherein
each of the brakes is actuated at the same pressure from a single output 208 from the pilot controlled relay
valve 198 and are thus all actuated at the same pressure, which pressure is a function of the pressure to
the pilot valve portion 202. Accordingly, as all of the brakes 190, 192, 194 and 196 are actuated at the same
pressure and as individual control of the actuating pressures thereof is not available in a standard trailer,
controlling the distribution of the braking effort between the trailer brakes to achieve intra-trailer balanced or
proportional braking on a controlled basis is not possible. However, by utilizing the tractor braking system
illustrated in Figure 6, inter-tractor-trailer proportional and, to a degree, balanced braking, is obtainable.

As may be seen from the equilibrium force diagrams of Figure 10, which do not include the
aerodynamic, grade or transient forces:

\[
\begin{align*}
H_1 &= -M_1a + H_F \\
V_1 &= M_1g + V_F \\
H_2 &= -M_2a - H_F \\
V_2 &= M_2g - V_F
\end{align*}
\]

where

\[
\begin{align*}
M_1 &= \text{mass of tractor 20} \\
M_2 &= \text{mass of trailer 30} \\
H_1 &= \text{braking force of tractor 28} \\
H_2 &= \text{braking force of trailer 30} \\
H_F &= \text{horizontal force at fifth wheel 34/king pin 178} \\
V_1 &= \text{weight supported by tractor axles} \\
V_2 &= \text{weight supported by trailer axles} \\
V_F &= \text{weight on fifth wheel} \\
g &= \text{gravity} \\
a &= \text{forward acceleration}
\end{align*}
\]

At tractor-trailer proportional braking conditions, the braking ratio of the tractor (taken as a unit) will be
equal to the braking ratio of the trailer (taken as a unit), or:

\[
H_1/V_1 = H_2/V_2
\]

Additionally, the braking ratio of the interconnecting assembly (H_F/V_F) will equal the same value, i.e.:

\[
H_F/V_F = H_2/V_2 = H_1/V_1
\]

Given the above relationships, it may be seen that, if H_F/V_F = -a, then tractor-trailer proportional braking

is achieved. Accordingly, by modulating the pressure applied to the tractor brakes (control of valves 108 and 168) and/or to the trailer brakes (control of valve 174), to minimize the error equation:

\[ E = H_F V_t C + a \]

tractor-trailer proportional braking, regardless of the load on the trailer, is provided and requires no additional sensors and/or control devices on the trailer. "C" is a weighing factor. Aerodynamic, grade and transient forces are not ignored but are calculated from force sensor data.

To achieve tractor-trailer balanced braking, with a trailer of unknown braking configuration, certain assumptions, inputs or calculated estimations are required as to the number and type of brakes with which the trailer brake system is equipped. The number and characteristics of the tractor brake system are known.

In a typical trailer brake system, for a given pilot pressure, all brakes are applied with the same pressure. Thus, other than to determine an average brake characteristic, knowing the number of trailer brakes (i.e. the number of brake equipped trailer axles) is not important to achieving an approximate tractor-trailer brake balance. By making certain calculations and/or assumptions as to trailer weight or mass, and by knowing the pressure supplied to each brake (i.e. pilot pressure to valve 198) to achieve a known vehicle deceleration, the number of brakes (i.e. 2, 4, 6...) and an average brake characteristic can be estimated with an acceptable accuracy. At that point, each brake can be assumed to be of an assigned average brake characteristic and the pressure from valve 198 will be the pressure required to cause each of the trailer brakes, on average, to do a total amount of brake work equal, or related in a predetermined manner, to the average brake work done by the tractor brakes.

Referring to Figure 8, a graphic chart illustrates the expected ranges of value of \( H_F \) for various numbers of trailer brakes for given pressure of trailer brake application with a known average tractor brake application and known or calculated tractor and trailer mass. Trailer mass may be calculated from \( H_F \) during a non-braking vehicle acceleration. Band 400 defines the expected response if the trailer has two braked wheels, band 402 defines the expected response if the trailer has four braked wheels and band 404 defines the expected response if the trailer has six braked wheels.

At a given trailer brake actuation pressure, for example 406, an \( H_F \) value 408 would indicate that the trailer has two braked wheels having relatively unaggressive brakes, an \( H_F \) of 409 would indicate that the trailer has six braked wheels having relatively aggressive brakes and an \( H_F \) value 410 would be read (according to predetermined rules) as either a trailer having four aggressive or six unaggressive wheels. Accordingly, a reading of an \( H_F \) value 410 may cause a predetermined average brake characteristic to be assigned.

Given a calculated or or assumed average trailer brake characteristic, the trailer brakes are actuated so that the average work (or other balanced parameter) done by each trailer brake is in a predetermined relationship to the average work (or other balanced parameter) done by the tractor brakes.

In slightly more sophisticated systems, the trailer may be equipped with an identifier socket 348 to mate with identifier plug 360 on the tractor which will provide certain basic trailer brake system information to the CPU 70 such as number of brakes, types of brakes, types of actuators, etc. This same information may be inputed to the CPU 70 by means of an operator keyboard 350. With this information, a more accurate trailer/tractor balanced braking can be achieved.

Accordingly, a braking system for a multi-vehicle system, such as a tractor-trailer truck 24 is provided that allows the inter-tractor-trailer braking effort to be distributed in a manner to achieve inter-tractor-trailer proportional braking or approximate inter-tractor-trailer balanced braking, depending upon operator demand, while utilizing special sensors and controls located solely on the tractor.

While the preferred embodiments of the present invention have been described in connection with specific apparatus, the descriptions are made by way of example only and not as limitations on the spirit and scope of the invention as hereinafter claimed.

Claims

1. A control system for a tractor-trailer brake system on a tractor-trailer vehicle (24) having an independently controllable tractor (28) sub-vehicle brake system comprising a known number of individually controllable brake sites (60, 62, 64, 66, 152, 154) having known brake characteristics, a fifth wheel connection (34) on the tractor sub-vehicle for engaging a king pin (176) carried by a trailer (30) sub-vehicle and means (174) for controlling an independently controllable trailer sub-vehicle brake system, said control system characterized by:
first sensing means (170, 172) mounted on said tractor sub-vehicle for providing input signals indicative of the value of the horizontal force and of the value of the vertical force at the fifth wheel/king pin connection, second sensing means (80) for providing an input signal indicative of the acceleration of the vehicle; third sensing means (76) for providing an input signal indicative of the level of braking effort demand by the operator;
a control unit (70) having means for receiving said input signals (72) and for processing said signals in accordance with predetermined logic rules to issue command output signals (74); and actuators (168, 174) responsive to said command output signals for modulating a controlled parameter at each sub-vehicle brake system related to the brake force at the sub-vehicle brake system;
said logic rules comprising comparing said demand input signal to a first reference value (A) and to a second reference value equal (B) to or greater than said first reference value, and if said demand signal is less than said first reference value causing each of the sub-vehicle brake systems to exert a brake force dependent upon the value of the demand input signal and independent of load, and if said demand signal is equal to or greater than said second reference value, causing each of the sub-vehicle brake system to exert a brake force directly related to the value of the demand input signal and to the load at the sub-vehicle brake system by modulating said brake forces to minimize the value of the equation:

\[ E = \frac{HF}{VF}C + a \]

where:

- \( E \) = error;
- \( C \) = a weighing factor;
- \( HF \) = horizontal force at fifth wheel/king pin connection;
- \( VF \) = load on fifth wheel; and,
- \( a \) = acceleration of vehicle;
said control unit also including logic rules for estimating trailer mass and for sensing input signals indicative of application force (406) applied to each trailer brake and the corresponding retarding force (408, 409, 410) of the trailer sub-vehicle brake system and comparing same to predetermined brake performance reference parameters (400, 402, 404) to estimate an average input/output characteristic for the trailer brakes on a trailer.

2. The control system of claim 1 wherein said first sensor means comprises transducers attached to said fifth wheel.

3. The control system of claim 2 wherein said second and said third sensing means are mounted on said tractor sub-vehicle.

4. The brake control system of claim 1 wherein trailer mass is estimated on the basis of the value of \( HF \) during nonbraking vehicle acceleration.

5. The brake control system of claim 1 wherein said trailer sub-vehicle is provided with an information storage device (380) readable by said control unit indicating at least the number of trailer brakes on the trailer.

6. The brake control system of claim 1 wherein if said demand signal is less than said first reference value, said control unit will cause each of said tractor brake sites to be actuated to provide a commanded brake work related in a predetermined manner to the commanded average brake work done by the trailer brakes based upon the estimated average input/output characteristic of the trailer brakes.

7. A control system for a tractor-trailer brake system on a tractor-trailer vehicle having an independently controllable tractor sub-vehicle brake system, a fifth wheel connection on the tractor for engaging a king pin carried by a trailer sub-vehicle and means for controlling an independently controllable trailer sub-vehicle brake system, said control system characterized by:

- first sensing means mounted on said tractor for providing input signals indicative of the value of the horizontal force and of the value of the vertical force at the fifth wheel/king pin connection,
- second sensing means mounted on said tractor for providing an input signal indicative of the acceleration of the vehicle;
- third sensing means mounted on said tractor for providing an input signal indicative of the level of braking effort demand by the operator; and
- a control unit having means for receiving said input signals and for processing said signals in accordance with predetermined logic rules to issue command output signals and actuators responsive to said command output signals for modulating a controlled parameter at each sub-vehicle brake system related to the brake
force at the sub-vehicle brake system; said logic rules comprising:
estimating the trailer mass on the basis of sensed values of horizontal force at the fifth wheel/king pin
connection during nonbraking vehicle acceleration; sensing an input signal indicative of application force
applied to each trailer brake and comparing same to predetermined brake performance reference param-
eters to estimate an average characteristic for the trailer brakes on a trailer;
comparing said demand input signal to a first reference value and if said demand signal is less than said
first reference signal, causing said trailer brakes and said tractor brakes to be applied such that the average
value at the trailer brakes of a selected parameter indicative of brake wear is related to the average value of
said parameter at the tractor brakes in a predetermined manner.
