(57) A method of providing a desired water level in a laundry machine by energising the motor of the machine intermittently to produce changes in velocity of the spin tub, agitator and a load of clothes in the spin tub. The changes in velocity are measured and from the measurements the mass of the load of clothes is determined. A desired volume of water necessary for an optimum wash of the load of clothes is then determined and this volume of water is admitted to the washing container of the laundry machine.

Abstract

A method of providing a desired water level in a laundry machine by energising the motor of the machine intermittently to produce changes in velocity of the spin tub, agitator and a load of clothes in the spin tub.

The changes in velocity are measured and from the measurements the mass of the load of clothes is determined. A desired volume of water necessary for an optimum wash of the load of clothes is then determined and this volume of water is admitted to the washing container of the laundry machine.

IMPROVEMENTS IN OR RELATING TO LAUNDRY MACHINES
AND/OR METHODS OF CONTROLLING THE SAME

This application is a division of Canadian Patent
Application Serial No. 2,024,025 filed 27 August 1990.

This invention relates to laundry machines and/or methods of controlling the same.

It is an object of the present invention to provide a laundry machine and/or methods of controlling the same which will at least provide the public with a useful choice.

Accordingly in one aspect the invention consists in a a method of providing a desired level of washing liquid in a laundry machine having a cabinet, a washing container within said cabinet, a rotatable assembly having a spin tub within said container and an agitator within said spin tub, a motor driving said agitator conjointly with said spin tub or separately on disconnection of said spin tub from said agitator as required, and washing liquid level control means to control washing liquid level in said washing container, the method comprising:

with a load of clothes in said spin tub, initiating supply of washing liquid to said container and energizing said motor intermittently to produce changes in the rotational speed of said rotatable assembly as washing liquid is being supplied to said container; sensing the changes in speed of said rotatable assembly relative to energy input to said motor with a sensing means being indicative of the resistance to rotation of said agitator; passing signals indicative of the resistance to rotation of said agitator to said control means which resistance to rotation is a measure of the viscosity of the mixture of clothes and washing liquid in said container; comparing the viscosity of said mixture with a desired viscosity; controlling the supply of further washing liquid to said container with said control means until said viscosity is equal to said desired viscosity to provide a required level of washing liquid; and causing continuous washing action to commence when said required level is reached.

In a further aspect the invention consists in control means for a laundry machine having a cabinet, a washing container within
5 said cabinet, a rotatable assembly comprising a spin tub within said container and an agitator within said spin tub, and a motor driving said agitator conjointly with said spin tub or separately on disconnection of said spin tub from said agitator as required, and washing liquid admission means, said control means comprising:

sensing means to sense the changes in speed of said rotatable assembly
10 including the mass of clothes load in said assembly relative to energy input to said motor; and washing liquid level control means arranged to control washing liquid level in said washing container in response to signals passed by said sensing means to said control means, the construction and arrangement being such that said control means energize said motor intermittently to sense the resistance to rotation of said agitator relative to energy input to said motor, receive signals indicative of the
15 resistance to rotation of said agitator from said sensing means which signals are a measure of the viscosity of the mixture of clothes and washing liquid in said container, compare the viscosity of said mixture with a desired viscosity, control the supply of further washing liquid to said container until said viscosity is equal to said desired viscosity to provide a desired level of washing liquid and cause continuous
20 washing action to commence when said desired level is reached.

In a still further aspect the invention consists in a laundry machine comprising:
a laundry machine comprising:

a cabinet; a washing container within said cabinet; a rotatable assembly comprising a spin tub within said container and an agitator within said spin tub; a motor driving said agitator conjointly with said spin tub or separately on
5 disconnection of said spin tub from said agitator as required; control means comprising sensing means to sense the changes in speed of said rotatable assembly including the mass of clothes load in said assembly relative to energy input to said motor; and washing liquid level control means arranged to control washing liquid level in said washing container in response to signals passed by said sensing means
10 to said control means, the construction and arrangement being such that said control means energize said motor intermittently to sense the resistance to rotation of said agitator relative to energy input to said motor after sensing said disconnection, receive signals indicative of the resistance to rotation of said agitator from said sensing means which signals are a measure of the viscosity of the mixture of clothes
15 and washing liquid in said container, compare the viscosity of said mixture with a desired viscosity, control the supply of further washing liquid to said container until said viscosity is equal to said desired viscosity to provide said desired level of washing liquid and cause continuous washing action to commence when said desired level is reached.

20 To those skilled in the art to which the invention relates, many changes in construction and widely differing embodiments and applications of the invention will suggest themselves without departing from the scope of the invention as defined in the appended claims. The disclosures and the descriptions herein are purely illustrative and are not intended to be in any sense limiting.

25

The invention consists in the foregoing and also envisages constructions of which the following gives examples only.

One preferred form of the invention will now be
5 described with reference to the accompanying drawings, in which;

Figure 1 is a cross sectional elevation of one form of laundry machine to which the invention is applicable,

Figure 2 is a flow chart of one form of control means
10 incorporated in the laundry machine of Figure 1,

Figure 3 is a flow chart of a further form of control means,

Figure 4 is a flow chart of a further form of control means,

15 Figure 5 is a flow chart of a part of the control means of Figures 2 to 4, and

Figures 6 and 7 are graphs of rotational velocity vs time of the rotatable assembly of the laundry machine of Figure 1.

20 Referring to the drawings, Figure 1 illustrates a cross section of a preferred form of laundry machine, a full description of which appears in published U.S. patent specification No.4,813,248 and the description of that laundry machine in that specification is incorporated
25 herein by reference.

For the purposes of the present invention the laundry machine comprises a cabinet 1 within which there is a fixed container 2 and within that container is a rotatable spin tub 3 and within the spin tub is an agitator 4. An
5 interengagement mechanism is provided to enable the spin tub 3 and the agitator 4 to be raised and lowered when washing liquids hereinafter referred to as water enters the container 1 and such mechanism includes an air chamber shown generally by the reference 5 and is described in the
10 said specification. The agitator 4 is driven by an electronically commutated motor 10, driving a shaft 11 carried in bearings 12. This construction is fully described in the above New Zealand patent specification which is incorporated herein by reference, including a
15 reference to parts of a dog clutch or inter engagement mechanism 13.

A control means 15 is provided preferably associated with the stator of the motor 10 and such control means include starting means arranged so that on appropriate
20 operation of manually operable controls in a console 16 by an operator, starting up of a washing cycle is commenced and water is admitted into the container 2 through a valve 17. Motor controls 19 including sensing means to sense changes in speed and energy input to said rotatable
25 assembly are also provided and the sensing means pass signals indicating these parameters to the control means.

The washing machine has washing liquid level detection means which comprise the spin tub 3, the disengagement of which from the agitator which is caused by its floating and the air chamber in liquid in the container disengaging the parts of the dog clutch mechanism 13 and also lifts the spin tub 3 and this is sensed by sensing means. The washing machine container 2 also has an auxiliary washing liquid level detection means comprising for example a pressure transducer 18 which provides the control means 15 with a signal indicative of the level of water in the container 2.

It has been found that there are three main methods by which the control means may determine the load in a washing machine and therefore control the supply of water or washing liquid to the level which provides the most effective wash performance.

In each method, the operator places a load e.g. of clothes in the spin tub 3 and appropriately operates the manual controls to give a desired wash.

In one form of the invention relating to a first control method, the control equipment includes a microprocessor programmed in accordance with a flow chart shown in Figure 2, and referring to that flow chart, the operator operates the appropriate controls in the console 16 such that the microprocessor enters the flow chart at the start, block 20. The microprocessor causes the

agitator and spin tub to rotate to a suitable speed e.g. approximately 100 rpm and the supply of power to the motor is controlled by the microprocessor to provide such a speed. Thus a certain amount of energy is imparted to the motor rotor, spin tub, and agitator which together comprise the rotatable assembly of the washing machine, and which, with the load of clothes, provide the initial resistance to rotation. Thus energy is imparted to the clothes in the spin tub. Changes in the velocity of the rotatable assembly correspond to changes in kinetic energy of the rotatable assembly and clothes load. Therefore if electrical energy is provided to the motor such that a certain velocity (and rotational kinetic energy) is attained, the time taken for the motor to coast to zero velocity will be a measure of the mass of the rotatable assembly and the load of clothes in the spin tub. The changes or rates of change of kinetic energy of the spin tub and contents are a measure of the mass of clothes therein. In Figure 2 the load size is determined at block 22 before water is supplied to the washing container.

Referring now to Figure 5 which a flow chart applicable to all three methods. This figure is a flow chart showing the steps involved in the preferred form of load determination according to the present invention.

The method of Figure 5 determines the changes in kinetic energy of the rotatable assembly comprising the

motor, drive shaft, interconnecting means, spin tub, agitator and clothes by supplying a minimum amount of energy to the motor such that the rotatable assembly approximates a predetermined velocity e.g. 40 rpm. The
5 motor and motor controls referred to in the specification are of the same form as those described in the specification of our New Zealand patent application No. 213489/213490 filed 16 September 1985, (US Patent No.4,857,814) which is incorporated herein by reference.
10 The predetermined velocity is stored in an information storage means comprising a memory of the microprocessor which controls the motor and is compared with the instantaneous velocity of the motor, which as described in the above specification is constantly calculated by the
15 microprocessor as part of the motor control system function. The motor control system thus provides sensing means which sense the kinetic energy of the rotatable assembly and provide signals indicating the mass of the rotatable assembly and the rotatable contents (clothes
20 load) thereof to the microprocessor. To enable the rotatable assembly to reach the predetermined velocity the pwm period is controlled, effectively controlling the current input to the motor as it is being commutated so that the velocity of the rotatable assembly slowly
25 increases. Referring to Figure 5, the algorithm there illustrated begins at the start block 50. Power is

supplied to the motor winding stages at block 51, as described above. It has been found that supplying a minimal amount of energy to the rotatable assembly is desirable, since large amounts of energy in the rotatable assembly mean measurements take a longer time to obtain. When power is supplied to the motor windings, the velocity of the motor and rotatable assembly is then monitored by the motor controller at block 52. A predetermined motor velocity e.g. 40 rpm is stored in the memory of the microprocessor and this predetermined velocity is compared at block 53 with the instantaneous motor velocity measured in block 52. When the motor velocity is equal to the predetermined motor velocity, power is removed from the windings and a timer begins at blocks 54 and 55. At this stage the motor velocity is still being measured. After power is removed from the windings the motor speed will gradually decrease until it eventually stops. The point at which the motor velocity reaches zero is determined at block 56 and at this point the timer is stopped at block 57 and the elapsed time is stored in the memory of the microprocessor. This cycle is repeated, the motor being energised and de energized intermittently.

Referring now to Figure 6 a graph of velocity vs time is shown, the origin representing the point at which the motor velocity is zero, before power is applied to the motor windings. The point 58 on the vertical velocity axis

represents the predetermined velocity and the point 59 on the horizontal time axis is a measure of the time taken to reach the predetermined velocity. When the rotatable assembly reaches the predetermined velocity 58 the pwm period is adjusted by means of the motor control system such that the predetermined velocity is maintained. The period for which this is maintained is shown as the time between points 59 and 60 in Figure 6. The points 59 and 60 could be substantially coincidental. The motor is then turned off at time 60 and allowed to coast. As soon as power is removed from the motor windings a timer is activated in the microprocessor and the back emf induced in the motor windings or the output of hall effect sensors mounted on the stator is monitored, so that the speed of rotation of the motor is known. When the rotatable assembly stops rotating the timer in the microprocessor records the time taken for the motor to decelerate to zero. This time may be for example, time 61 or 62 shown in Figure 6 and this time is representative of the inertia of the rotatable assembly. For example, if there is a large mass of clothes in the spin tub then the inertia of the rotatable assembly will be greater and the time taken for the rotational velocity of the rotatable assembly to reach zero will be significantly longer than the time taken if the spin tub had no clothes therein, for example. Since at this point in the wash cycle the agitator and spin tub are

interconnected and the inertia of this apparatus is constant, the only factor which will change the time taken for the motor speed to ramp down will be the load of clothes in the spin tub and therefore the load is known.

5 However, due to some spurious variables such as the changing position of the clothes within the spin tub, any one reading of the time taken for the speed of the motor to reach zero will not necessarily be precisely representative of the load of clothes in the spin tub. Therefore it has
10 been found that a number of readings e.g. at least one reading in each direction of rotation is desirable in order to obtain a true indication of the load of clothes in the machine. If the readings in each direction provide times which are within acceptable tolerances of each other, then
15 these times are compared with time values stored in look up tables in the memory of the microprocessor which provide the control system with an indication of the load of clothes in the machine and therefore the water level which will be required for the wash routine for that load to
20 commence. Once the appropriate water level is known by the control system the wash profile of agitation stroke time, desired speed of rotation and acceleration is selected in accordance with the specification of our New Zealand patent application No.213489/213490.

25 Although in this form of the invention load measuring may be carried out with the load of clothes dry, the

accuracy of load measurements may also be increased by dampening the clothes before taking the measurements. Such dampening is effected by rotating the spin tub slowly while spraying water from the outlet of valve 17 over the clothes
5 in the spin tub.

Once the load size check has been carried out at block 22 of Figure 2 the microprocessor causes valve 17 to be opened by a signal from the "water on" block 23. Slow stirring with reversals or with intermittent supply of
10 power is carried on at block 24 as has been described above. At this point the load comprises clothes and water. The change in kinetic energy is continuously checked as shown by the circuit 25 containing the slow stir routine at 24. The declutch and disconnection of the agitator 4 from
15 the spin tub 3 is detected by the air chamber or float 5 interrogation at 26. The spin tub and the agitator are connected together by the mechanism 13 and initially a relatively large inertia is present in the associated spin tub agitator and load of clothes. The inertia of the
20 rotatable assembly and load is measured as a change in kinetic energy when the power to the motor is cut off and the motor is allowed to slow to zero speed after being maintained at a predetermined velocity as described above. The water level in the container increases until the float
25 5 floats the spin tub upwardly in a manner such as to disconnect the interconnecting means between the agitator

and the spin tub. When this disconnection occurs there is a sudden decrease in the inertia of the rotatable assembly which is detected by the sensing means. Referring again to Figure 6, the disconnection is seen by the sensing means as a sudden decrease in the time taken for the rotatable assembly to decelerate from the predetermined velocity to zero. The time taken for the rotatable assembly to decelerate after disconnection may for example be only one tenth that taken prior to disconnection. Thus the time between points 60 and 62 in Figure 6 may represent the time taken for the rotatable assembly to decelerate when the spin tub and agitator are interconnected and the time between points 61 and 60 may represent the time taken for the rotatable assembly to decelerate after declutching has occurred. Thus it can be seen that there is a clear indication provided to the sensing means that disconnection has occurred.

It should be noted that the time taken for the rotatable assembly to accelerate to the predetermined speed may also be used as an indication of the inertia of the rotatable assembly and water and clothes therein. The change in the time required to accelerate the rotatable assembly is not shown in Figure 6 in order to simplify the diagram.

Referring now to Figure 7, the time required for the rotatable assembly of clothes load to reach the

predetermined velocity 58 prior to disconnection is the time between the origin and point 63. If the same torque is applied to the motor after disconnection the time taken to reach velocity 58 is that between the origin and point 59. Again the disconnection of the spin tub from the agitator is sensed, the signal change indicated to the control means where, by reference to the look up tables, a water level for the load is selected. The ramp down times are not shown for simplicity.

Thus when declutching occurs a further timer commences operation, allowing the water supply to remain on for a desired water on overrun time, which is either a predetermined period, or is of say 10-20% of the time to fill the container 2 to declutch. The water on overrun time is operated in block 27 and when that time has elapsed at block 28 the "water off" signal operates at 29 causing valve 17 to close. The load measured from block 22 indicates the washing profile at block 30 and washing started at block 31. The washing profile control is described in the specification of our New Zealand patent application No. 213489/213490.

Thus in this first method the water level is determined by adding water after declutching for a period of time which is either a proportion of the time to fill to declutching or a fixed further period of time dependent on the sensed load in the machine.

Referring again to Figure 1, water pressure indicator 18 senses pressure of water in the base of the washing container and therefore also provides an indication of the water level in the container 2. If the pressure indicator 18 is present, the routine to time further water supply in block 27 is not necessary and a branch may be taken from block 26 to block 32 (dashed lines) which checks the water level indicator and compares this at block 33 with the desired water level which has been obtained from look up tables relating to the load size stored in information storage means which comprise the memory of the microprocessor. If the correct water level has been reached the water off block is returned to at 29, the wash profile is set by reference to the look up tables and the wash begins.

Although the load of clothes in the spin tub may be sensed before water is added to the spin tub by the method previously described, a second method of determining the load of clothes in the spin tub is to start the washing machine motor from a stand still as previously described but in addition, substantially simultaneously or earlier admitting water to the container, increasing the rotational velocity of the motor up until a predetermined velocity is obtained and then measuring the time taken for the rotational velocity to drop to zero, as the water is being allowed to enter the washing container. When a certain

known quantity of water is present in the container, float
5 will rise and the spin tub will be disconnected from the
agitator such that the spin tub is stationary. As with the
first method since the spin tub comprises a significant
5 proportion of the mass of the rotatable assembly, the
inertia of the assembly will suddenly decrease and after
the predetermined velocity is reached, the time taken for
the rotatable assembly to come to a halt will suddenly
decrease by a significant time period. The microprocessor
10 has in its memory a figure representative of a sufficiently
large time period such that if the measured time period
decreases by an amount which is equal to or greater than
the value stored in a memory of the microprocessor, the
microprocessor will signal that disconnection of the spin
15 tub from the agitator has occurred. The amount of water
necessary for disconnection to occur will vary depending on
the load of clothes in the spin tub. The microprocessor
has stored the time value indicative of the total load of
the rotatable assembly from the last iteration prior to
20 disconnection. Thus the load of clothes and water in the
machine is known just prior to disconnection. Since the
time from when water was first introduced to the container
to the time at which disconnection occurs is a relative
measure of the load of clothes in the spin tub depending on
25 the rate of water flow into the machine, the microprocessor
may now refer to a look up table in order to obtain a value

of the time required to fill the container to a desired water level. The look up table in the microprocessor provides a further "water on" time after disconnection which is a percentage overrun time based on the time taken
5 to fill the container to declutch.

In the routine of Figure 3, as stated above, operating the controls causes a routine to start at 20 and the microprocessor causes the valve 17 to be opened by a signal from the "water on" block 21. Before load measurement
10 begins the spin tub may be rotated slowly such that the outlet of valve 17 sprays water on top of the clothes in the container in order to ensure that the clothes are uniformly wet before load measurement begins. In addition slow stirring is commenced by a signal from block 35, such
15 slow stir includes acceleration and deceleration sequences during which there are changes in kinetic energy and the speed changes and the mass of the load can be indicated by sensing means which sense the changes in kinetic energy over a predetermining timer or between predetermined
20 speeds. As explained above with reference to Figures 5 and 6, signals indicating the changes in kinetic energy are then passed from block 36. The spin tub and the agitator are connected together by the mechanism 13 and initially a relatively large inertia is present in the associated spin
25 tub agitator and load of clothes. This inertia is measured for example as a change in kinetic energy when the power to

the motor is cut off and allowed to slow to zero speed as previously described. The water level in the container increases, until the float 5 floats the spin tub upwardly in a manner such as to disconnect the interconnecting means between the agitator and spin tub. At this point there is a sudden decrease in the inertia of the rotatable assembly and this decrease in inertia is detected by the sensing means and instead of the microprocessor indicating that the slow stir is to continue, causes at 37 a signal to be passed by block 36 indicating that disconnection has occurred as indicated by the block 38. The momentum or kinetic energy signal reached in the final stages before declutching is recorded at block 38 and is passed to block 42. The mass of the clothes load in the spin tub has been found by experiment to be directly proportional to the quantity of water required to float the spin tub. The water or washing liquid is supplied to the container at a fixed rate and therefore the time between turning the water valve "on" and disconnection is also an indication of the load of clothes in the container. Since the water level at disconnection is known from pressure indicator 18 the load of clothes is known and the control means can supply the appropriate water level for washing. If water pressure indicator 18 is not present the mass of the clothes load and the desired washing water level may be calculated by the control means eg. by the look up tables in the

microprocessor since the relationship between water level at disconnection and clothes load is known and the total load of water and clothes is known at disconnection. The operator will have selected a desired degree of

5 vigorousness of wash and this vigorousness is affected by the momentum of the spin tub, agitator, clothes and water contained at the declutch level. Accordingly a desired rotary stroke of the agitator during washing is set up according to the momentum figure stored in block 42 as is

10 described in New Zealand patent specification No. 213489/213490.

Once disconnection or declutching has occurred according to signals from block 36, (and the timing of such disconnection depends on the size of the clothes load) the

15 microprocessor continues to check the load which is still influenced by the filling of water into the container 2 as is indicated in block 39 and the microprocessor determines at block 40 as to whether a desired water level and load measurement has been reached. This is achieved by means of

20 the water pressure indicator 18 from which the microprocessor has determined the water level at disconnection. Knowing the water level at this point means that the load of clothes in the spin tub is known and the microprocessor then refers to a look up table to determine

25 the desired water level. The water level may then be monitored by checking the pressure indicator at block 39.

Also, once the time to declutch is known the correct water level may be reached by timing the further water supply as shown in the block 44 with dashed lines, this time being an empirically decided percentage overrun time from the time
5 taken for declutch to occur. When the correct water level has been reached in block 45 the water valve 17 is turned off in block 41 and the wash begins in block 43.

Referring now to Figure 4, a third method of determining the load in the washing machine is shown. As
10 with Figures 2 and 3 the routine starts at block 20 and water is turned on at block 21. The slow stir with changes in speed of the rotatable assembly and corresponding changes in kinetic energy as described with reference to Figures 5 and 6 is initiated in block 58. The load
15 measurement is updated in block 59 and declutching is detected in block 60. When the water is turned on in block 21 and before the slow stir begins in block 58 the spin tub is rotated slowly for a brief period so that the water coming in through valve 17 is sprayed onto the clothes in
20 the spin tub to ensure that the clothes are substantially uniformly wet before load measurements are taken. Thus initially, there are wet clothes about the agitator and between the agitator and the walls of the spin tub. When disconnection occurs there will be some water in the
25 container 2 and there will still be clothes between the agitator and the spin tub such that the agitator movement

is restricted by the clothes. As more water is introduced into the container, the clothes in the spin tub will begin to float free from the agitator and thus the increased water in the container reduces the friction between the agitator and the walls of the spin tub. Therefore if the agitator is rotated to a certain low velocity and power is removed from the motor, allowing the motor and agitator to coast, the time taken for the agitator to reach zero velocity will gradually increase as more water is introduced into the container. Therefore the measurements that began as measurements of the mass of the rotatable assembly, clothes and water before disconnection become measurements of the friction between the agitator and spin tub due to the clothes and water in the container. These measurements may also be thought of as measurements of the "viscosity" of the mixture of clothes and water in the washing container. When the time taken for the agitator to reach zero velocity is sufficiently long then the optimum water level has been reached for good wash performance. The load measurement on the agitator is compared with the optimum stored in the microprocessor at block 61 and if the load measurement is satisfactory the water valve 17 is switched off at block 62. The load measurement obtained in block 59 may be passed to block 63 to give a measure of the load size to set the initial wash profile. Alternatively, the water pressure indicator 18 may be monitored in order

to determine the water level reached and from this water level the desired initial wash profile may be determined. The wash then begins in block 64.

5 After the washing container has been filled to the desired level and before the wash begins the clothes in the washing container will often have a number of air bubbles therein and when agitation begins these will be expelled and the water level in the container may drop significantly. Therefore in each of the methods described,
10 in machines which are provided with a water pressure indicator 18, before the wash is started the agitator is rotated back and forth a small number of strokes in order to expel the air trapped in the clothes in the spin tub. Once the air is removed the water valve 17 is turned on
15 again in order to refill the water container 2 to the desired level.

From the foregoing it will be seen that methods of providing an optimum water level for a load of clothes in a washing machine are provided which are performed
20 automatically by the machine without any necessary information or decisions being supplied by the operator, other than decisions regarding vigourousness of wash.

We claim:

1. A method of providing a desired level of washing liquid in a laundry machine having a cabinet, a washing container within said cabinet, a rotatable assembly having a spin tub within said container and an agitator within said spin tub, a motor driving said agitator conjointly with said spin tub or separately on disconnection of said spin tub from said agitator as required, and washing liquid level control means to control washing liquid level in said washing container, the method comprising:

with a load of clothes in said spin tub, initiating supply of washing liquid to said container and energizing said motor intermittently to produce changes in the rotational speed of said rotatable assembly as washing liquid is being supplied to said container; sensing the changes in speed of said rotatable assembly relative to energy input to said motor with a sensing means being indicative of the resistance to rotation of said agitator; passing signals indicative of the resistance to rotation of said agitator to said control means which resistance to rotation is a measure of the viscosity of the mixture of clothes and washing liquid in said container; comparing the viscosity of said mixture with a desired viscosity; controlling the supply of further washing liquid to said container with said control means until said viscosity is equal to said desired viscosity to provide a required level of washing liquid; and causing continuous washing action to commence when said required level is reached.

2. A method as claimed in claim 1 and further comprising:

determining the point of disconnection of said spin tub from said agitator by passing signals indicative of the total rotating mass of said rotatable assembly including the washing

liquid in said container and the clothes in said spin tub from said sensing means to said control means; and detecting a sudden change in said total rotating mass.

3. A method as claimed in claim 1 wherein:

sensing said resistance to rotation of said agitator comprises controlling the supply of power to said motor with said control means so that said agitator is accelerated to a desired rotational velocity, removing power from the motor, measuring the time taken for the agitator to attain zero rotational velocity, said time indicating said viscosity, passing said time to said control means as said signal and repeating said steps to obtain further time measurements as required.

4. A method as claimed in claim 1 wherein:

sensing said total rotating mass of said rotatable assembly comprises controlling the supply of power to said motor with said control means so that said rotatable assembly is accelerated to a desired rotational velocity, removing power from the motor, measuring the time taken for the rotatable assembly to attain zero rotational velocity, said time indicating total rotating mass, passing said time to said control means and said signal, and repeating said steps to obtain further time measurements as required.

5. A method as claimed in claim 1 wherein:

sensing said resistance to rotation of said agitator comprises controlling the supply of power to said motor with said control means so that said agitator is accelerated to a desired rotational velocity, measuring the time taken for said agitator to attain said desired velocity, said time indicating

said viscosity, passing said time to said control means as said signal, and repeating said steps to obtain further time measurements as required.

6. A method as claimed in claim 1 wherein:

sensing said total rotating mass of said rotatable assembly comprises controlling the supply of power to said motor with said control means so that said rotatable assembly is accelerated to a desired rotational velocity, measuring the time taken for the rotatable assembly to attain said desired velocity, said time indicating said total rotating mass, passing said time to said control means as said signal, and repeating said steps to obtain further time measurements as required.

7. A method as claimed in claim 1 and further comprising:

using signals passed to said control means from said sensing means at the time of disconnection to determine the mass of the load of clothes, storing information of the mass of the load of clothes in information storage means and using the stored information to provide routines selected from giving an indication of a wash profile of agitation stroke times, desired speed of rotation and acceleration requested for the sensed selected load of clothes to be washed and to control the washing routine to give a desired degree of wash to the clothes.

8. A method as claimed in claim 1 and further comprising:

rotating said spin tub slowly in one direction and supplying a desired quantity of washing liquid to said container before energizing said motor so that said load of clothes is damp before intermittent energization of said motor.

9. A method as claimed in claim 1 and further comprising commencing a gentle wash agitation of the clothes for a predetermined time after said control means have supplied washing liquid to said container to said desired level; stopping said gentle wash agitation; detecting the washing liquid level in said container; and if said washing liquid level is below said desired level, supplying further washing liquid to said container so that said washing liquid level becomes said desired level, and when said washing liquid is at said desired level, causing continuous washing action to commence.

10. Control means for a laundry machine having a cabinet, a washing container within said cabinet, a rotatable assembly comprising a spin tub within said container and an agitator within said spin tub, and a motor driving said agitator conjointly with said spin tub or separately on disconnection of said spin tub from said agitator as required, and washing liquid admission means, said control means comprising:

sensing means to sense the changes in speed of said rotatable assembly including the mass of clothes load in said assembly relative to energy input to said motor; and washing liquid level control means arranged to control washing liquid level in said washing container in response to signals passed by said sensing means to said control means, the construction and arrangement being such that said control means energize said motor intermittently to sense the resistance to rotation of said agitator relative to energy input to said motor, receive signals indicative of the resistance to rotation of said agitator from said sensing means which signals are a measure of the viscosity of the mixture of clothes and washing liquid in said container, compare the viscosity of said mixture with a desired viscosity, control the supply of further washing liquid to said container

until said viscosity is equal to said desired viscosity to provide a desired level of washing liquid and cause continuous washing action to commence when said desired level is reached.

11. Control means as claimed in claim 10 and further comprising:

means for determining the point of disconnection of said spin tub from said agitator by receiving signals indicative of the total rotating mass of said rotatable assembly including the washing liquid in said container and the clothes in said spin tub from said sensing means, and detecting a sudden change in said total rotating mass.

12. Control means as claimed in claim 10 and further comprising:

means for sensing said resistance to rotation of said agitator by controlling the supply of power to said motor such that said agitator is accelerated to a desired rotational velocity, removing power from the motor, measuring the time taken from the agitator to attain zero rotational velocity, said time indicating said resistance to rotation, and passing said time to said control means as said signal.

13. Control means as claimed in claim 11 and further comprising:

means for sensing said total rotating mass of said rotatable assembly by controlling the supply of power to said motor so that said rotatable assembly is accelerated to a desired rotational velocity, removing power from the motor, measuring the time taken for the rotatable assembly to attain zero rotational velocity, said time indicating said total

rotating mass, and passing said time to said control means as said signal.

14. Control means as claimed in claim 10 and further comprising:

means for sensing said resistance to rotation of said agitator by controlling the supply of power to said motor so that said motor is accelerated to a desired rotational velocity, measuring the time taken for the agitator to attain said desired velocity, said time indicating said resistance to rotation, and passing said time to said control means as said signal.

15. Control means as claimed in claim 11 and further comprising:

means for sensing said total rotating mass of said rotatable assembly by controlling the supply of power to said motor so that said rotatable assembly is accelerated to a desired rotational velocity, measuring the time taken for the rotatable assembly to attain said desired velocity, said time indicating said total rotating mass, and passing said time to said control means as said signal.

16. Control means as claimed in claim 10 and further comprising:

information storage means for storing of information of the mass of the load of clothes responsive to said signals passed to said control means from said sensing means at the time of disconnection and using the stored information to provide routines selected from giving an indication of a wash profile of agitation stroke times, desired speed of rotation and acceleration required for the sensed selected load of clothes to

be washed and to control the washing routine to give a desired degree of wash to the clothes.

17. Control means as claimed in claim 10 and further comprising:

means for rotating said spin tub slowly in one direction and supplying a desired quantity of washing liquid to said container before energizing said motor intermittently so that said load of clothes is damp before intermittent energization of said motor.

18. Control means as claimed in claim 11 and further comprising:

means for commencing a gentle wash agitation of the clothes for a predetermined time after said washing liquid has been supplied to said container to said desired level; stopping said gentle wash agitation; detecting the washing liquid level in said container; and if said washing liquid level is below said desired level, supplying further washing liquid to said container so that said washing liquid level becomes said desired level, and when said washing liquid is at said desired level, causing continuous washing action to commence.

19. A laundry machine comprising:

a cabinet; a washing container within said cabinet; a rotatable assembly comprising a spin tub within said container and an agitator within said spin tub; a motor driving said agitator conjointly with said spin tub or separately on disconnection of said spin tub from said agitator as required; control means comprising sensing means to sense the changes in speed of said rotatable assembly including the mass of clothes load in said assembly relative to energy input to said motor;

and washing liquid level control means arranged to control washing liquid level in said washing container in response to signals passed by said sensing means to said control means, the construction and arrangement being such that said control means energize said motor intermittently to sense the resistance to rotation of said agitator relative to energy input to said motor after sensing said disconnection, receive signals indicative of the resistance to rotation of said agitator from said sensing means which signals are a measure of the viscosity of the mixture of clothes and washing liquid in said container, compare the viscosity of said mixture with a desired viscosity, control the supply of further washing liquid to said container until said viscosity is equal to said desired viscosity to provide said desired level of washing liquid and cause continuous washing action to commence when said desired level is reached.

20. A laundry machine as claimed in claim 19 wherein:

said control means further comprises means for determining the point of disconnection of said spin tub from said agitator by receiving signals indicative of the total rotating mass of said rotatable assembly including the washing liquid in said container and the clothes in said spin tub from the sensing means, and detecting a sudden change in said total rotating mass.

21. A laundry machine as claimed in claim 19 wherein:

said control means further comprise means for sensing said resistance to rotation of said agitator by controlling the supply of power to said motor so that said agitator is accelerated to a desired rotational velocity, removing power from the motor, measuring the time taken for the agitator to attain zero rotational velocity, said time indicating said

resistance to rotation, and passing said time to said control means as said signal.

22. A laundry machine as claimed in claim 20 wherein:

said control means further comprise means for sensing said total rotating mass of said rotatable assembly by controlling the supply of power to said motor so that said agitator is accelerated to a desired rotational velocity, removing power from the motor, measuring the time taken for the agitator to attain zero rotational velocity, said time indicating said resistance to rotation, and passing said time to said control means as said signal.

23. A laundry machine as claimed in claim 19 wherein:

said control means further comprise means for sensing said resistance to rotation of said agitator by controlling the supply of power to said motor so that said agitator is accelerated to a desired rotational velocity, measuring the time taken for the agitator to attain said desired velocity, said timer indicating said resistance to rotation, and passing said control means as said signal.

24. A laundry machine as claimed in claim 20 wherein:

said control means further comprise means for sensing said total rotating mass of said rotatable assembly by controlling the supply of power to said motor so that said rotatable assembly is accelerated to a desired rotational velocity, measuring the time taken for the rotatable assembly to attain said desired velocity, said timer indicating said total rotating mass, and passing said time to said control means as said signal.

25. A laundry machine as claimed in claim 19 and further comprising:

information storage means for storing of information of the mass of the load of clothes responsive to said signals passed to said control means from said sensing means at the time of disconnection and using the stored information to provide routines selected from giving an indication of a wash profile of agitation stroke times, desired speed of rotation and acceleration required for the sensed selected load of clothes to be washed and to control the washing routine to give a desired degree of wash to the clothes.

26. A laundry machine as claimed in claim 19 and further comprising:

means for rotating said spin tub slowly in one direction and supplying a desired quantity of washing liquid to said container before energizing said motor intermittently so that said load of clothes is damp before intermittent energization of said motor.

27. A laundry machine as claimed in claim 19 and further comprising:

means for commencing a gentle wash agitation of the clothes for a predetermined time after said washing liquid has been supplied to said container to said desired level; stopping said gentle wash agitation; detecting the washing liquid level in said container; and when said washing liquid level is below said desired level, supplying further washing liquid to said container so that said washing liquid level becomes said desired level, and when said washing liquid is at said desired level, causing continuous washing action to commence.
