This invention relates to improvements in advertising equipment and more particularly to point-of-sale merchandise holders used in grocery stores, and especially in super-markets. Such an enormous number of items is sold in these stores, it is desirable to have a holder that is sufficiently durable and cheap enough for the intended purpose, and is attractive in appearance, and I have found a relatively hard plastic will serve this purpose and hold its shape well.

Each receptacle has a front wall, a rear wall, 2 substantially parallel thereto, top and bottom walls 3 and 4 in parallel relation and connecting said top and bottom walls to form an approximately box-like structure.

In order to decrease the amount of material used, said bottom wall may have one or more cut-outs 5 therethrough.

The ends of each receptacle are indicated at 6 and 7, respectively, and the receptacles are open from end-to-end as indicated at 8, so as to in effect, form a tubular structure.

An opening 9 is cut through each top wall, extending from one terminal edge 6 to a spaced distance from the other end 7. It is obvious that said receptacles may be adjustably moved horizontally so that both openings taken together form the enlarged opening 9 aforesaid, said larger opening being of proper size to accommodate the width of the cards 10 that form the supply from which individual ones are withdrawn.

The top and bottom edges of each receptacle are provided with forwardly projecting flanges 11—11 having a groove or track 12 therein-long, these top and bottom grooves opposing one another, as shown.

To interlock the receptacles in their horizontally adjusted spaced-apart relation, a display card 13 of a width slightly greater than the distance between said top and bottom flanges, may be flexed sufficiently, as shown in dotted lines in FIG. 2, so as to pass the foremost edges of said flanges, whereupon freeing said card will permit the latter to spring into said grooves, as shown in full lines.

The terminal ends of said card 13 is extended at its top and bottom to form ears or tabs 14, 14 that serve as limit stops to prevent separation of the receptacle members.

To mount the device on said horizontally projecting portion of the shelf or the like, clips 15 are provided to extend rearwardly from each rear wall 2, said clips having top and bottom fingers so spaced apart that they will frictionally engage said shelf and straddle the same.

Another display card 16, preferably wider and higher than said cards that are to be withdrawn, may be carried at the rear of the device, as by forming a lip 17 extending upright along the juncture of the upper finger and the rear wall, preferably projecting slightly rearwardly toward its free edge, to tend to press against said display card 16 after the latter has been put into position.

The entire device may be pre-assembled if desired, with the cards 13 and 16 in place, before pressing the said device onto said projecting shelf portion.

1. A holder for successive withdrawal of individual cards therefrom, and adapted to be suspended by a horizontally projecting shelf, comprising a pair of like opposed hollow box-like receptacles laterally adjustably movable relatively of one another, each receptacle having substantially parallel front and rear walls, a top and a bottom wall and open at one end, and legs carried by said rear walls to clamp on said shelf, said top walls having an opening therethrough extending from said opposed open ends and terminating at a spaced distance from their other ends whereby said receptacles may be adjustably moved relatively of one another to receive a supply of said cards of pre-determined width through said combined top openings, and a display card whose length is greater than that of said combined top opening and engaging and interlocking with said pair of receptacles for detachably maintaining the latter in their spaced apart adjusted relation.
2. A holder as set forth in claim 1, further characterized in that the front walls of said receptacles have grooves extending along their top and bottom edges so that said display card may engage in said grooves.

3. A holder as set forth in claim 2, further characterized in that said display card is slightly wider than the distance between said top and bottom grooves, whereby said display card may be flexed sufficiently in width to permit of its engagement within said grooves.

4. A holder as set forth in claim 3, further characterized in that said display card has vertically extending end tabs to abut the terminal ends of said grooves to limit separation of said receptacles.

5. A holder as set forth in claim 1, further characterized in that each receptacle has said pair of legs projecting therefrom for frictionally straddling said shelf, and a resiliently yieldable lip along the juncture of each rear wall with one of said legs to engage a second display card placed between said lip and rear wall.
