BACKGROUND OF THE INVENTION

Mammalian protein kinases are important regulators of cellular functions. Because dysfunctions in
protein kinase activity have been associated with several diseases and disorders, protein kinases are targets for
drug development.

The tyrosine kinase receptor, FMS-like tyrosine kinase 3 (FLT3), is implicated in cancers, including
leukemia, such as acute myeloid leukemia (AML), acute lymphoblastic leukemia (ALL), and myelodysplasia.
About one-quarter to one-third of AML patients have FLT3 mutations that lead to constitutive activation of the
kinase and downstream signaling pathways. Although in normal humans, FLT3 is expressed mainly by normal
myeloid and lymphoid progenitor cells, FLT3 is expressed in the leukemic cells of 70-80% of patients with
AML and ALL. Inhibitors that target FLT3 have been reported to be toxic to leukemic cells expressing mutated
and/or constitutively-active FLT3. Thus, there is a need to develop potent FLT3 inhibitors that may be used to
treat diseases and disorders such as leukemia.

The Abelson non-receptor tyrosine kinase (c-Abl) is involved in signal transduction, via
phosphorylation of its substrate proteins. In the cell, c-Abl shuttles between the cytoplasm and nucleus, and its
activity is normally tightly regulated through a number of diverse mechanisms. Abl has been implicated in the
control of growth-factor and integrin signaling, cell cycle, cell differentiation and neurogenesis, apoptosis, cell
adhesion, cytoskeletal structure, and response to DNA damage and oxidative stress.

The c-Abl protein contains approximately 1150 amino-acid residues, organized into an N-terminal cap
region, an SH3 and an SH2 domain, a tyrosine kinase domain, a nuclear localization sequence, a DNA-binding
domain, and an actm-bnding domain.

Chronic myelogenous leukemia (CML) is associated with the Philadelphia chromosomal
translocation, between chromosomes 9 and 22. This translocation generates an aberrant fusion between the bcr
 gene and the gene encoding c-Abl. The resultant Bcr-Abl fusion protein has constitutively active tyrosine-
kinase activity. The elevated kinase activity is reported to be the primary causative factor of CML, and is
responsible for cellular transformation, loss of growth-factor dependence, and cell proliferation.

The 2-phenylaminopyrimidine compound imatinib (also referred to as STI-571, CGP 57148, or
Gleevec) has been identified as a specific and potent inhibitor of Bcr-Abl, as well as two other tyrosine kinases,
c-kit and platelet-derived growth factor receptor. Imatinib blocks the tyrosine-kinase activity of these proteins.
Imatinib has been reported to be an effective therapeutic agent for the treatment of all stages of CML. However,
the majority of patients with advanced-stage or blast crisis CML suffer a relapse despite continued imatinib
therapy, due to the development of resistance to the drug. Frequently, the molecular basis for this resistance is the emergence of imatinib-resistant variants of the kinase domain of Bcr-Abl. The most commonly observed underlying amino-acid substitutions include Glu255Lys, Thr315Ile, Tyr293Phe, and Met351Thr.

MET was first identified as a transforming DNA rearrangement (TPR-MET) in a human osteosarcoma cell line that had been treated with N-methyl-N'-nitro-nitrosoguanidine (Cooper et al. 1984). The MET receptor tyrosine kinase (also known as hepatocyte growth factor receptor, HGFR, MET or c-Met) and its ligand hepatocyte growth factor ("HGFi") have numerous biological activities including the stimulation of proliferation, survival, differentiation and morphogenesis, branching tubulogenesis, cell motility and invasive growth. Pathologically, MET has been implicated in the growth, invasion and metastasis of many different forms of cancer including kidney cancer, lung cancer, ovarian cancer, liver cancer and breast cancer. Somatic, activating mutations in MET have been found in human carcinoma metastases and in sporadic cancers such as papillary renal cell carcinoma. The evidence is growing that MET is one of the long-sought oncogenes controlling progression to metastasis and therefore a very interesting target. In addition to cancer there is evidence that MET inhibition may have value in the treatment of various indications including: Listeria invasion, Osteolysis associated with multiple myeloma, Malaria infection, diabetic retinopathies, psoriasis, and arthritis.

The tyrosine kinase RON is the receptor for the macrophage stimulating protein and belongs to the MET family of receptor tyrosine kinases. Like MET, RON is implicated in growth, invasion and metastasis of several different forms of cancer including gastric cancer and bladder cancer.

The Aurora family of serine/threonine kinases is essential for mitotic progression. Expression and activity of the Aurora kinases are tightly regulated during the cell cycle. A variety of proteins having roles in cell division have been identified as Aurora kinase substrates. Based on the known function of the Aurora kinases, inhibition of their activity is believed to disrupt the cell cycle and block proliferation and therefore tumor cell viability. Harrington et al., Nature Medicine, advanced publication online (2004).

3-Phosphoinositide-dependent kinase 1 (PDK1) is a Ser/Thr protein kinase that can phosphorylate and activate a number of kinases in the AGC kinase super family, including Akt/PKB, protein kinase C (PKC), PKC-related kinases (PRK1 and PRK2), p70 ribosomal S6-kinase (S6K1), and serum and glucocorticoid-regulated kinase (SGK). The first identified PDK1 substrate is the proto-oncogene Akt. Numerous studies have found a high level of activated Akt in a large percentage (30-60%) of common tumor types, including melanoma and breast, lung, gastric, prostate, hematological and ovarian cancers. The PDK1/Akt signaling pathway thus represents an attractive target for the development of small molecule inhibitors that may be useful in the treatment of cancer. Feldman et al., JBC Papers in Press. Published on March 16, 2005 as Manuscript MS01367200.

Because kinases have been implicated in numerous diseases and conditions, such as cancer, there is a need to develop new and potent protein kinase inhibitors that can be used for treatment. The present invention fulfills these and other needs in the art. Although certain protein kinases are specifically named herein, the present invention is not limited to inhibitors of these kinases, and, includes, within its scope, inhibitors of related protein kinases, and inhibitors of homologous proteins.

DETAILED DESCRIPTION OF THE INVENTION

Definitions

Abbreviations used herein have their conventional meaning within the chemical and biological arts.

Where substituent groups are specified by their conventional chemical formulae, written from left to right, they equally encompass the chemically identical substituents that would result from writing the structure from right to left, e.g., -CH_2O- is equivalent to -OCH_2-.

The term "alkyl," by itself or as part of another substituent, means, unless otherwise stated, a straight (i.e. unbranched) or branched chain, or cyclic hydrocarbon radical, or combination thereof, which may be fully saturated, mono- or polyunsaturated and can include di- and multivalent radicals, having the number of carbon atoms designated (i.e. C_1-C_10 means one to ten carbons). Examples of saturated hydrocarbon radicals include, but are not limited to, groups such as methyl, ethyl, n-propyl, isopropyl, n-butyl, t-butyl, isobutyl, sec-butyl, cyclohexyl, (cyclohexyl)methyl, cyclopropylmethyl, homologs and isomers of, for example, n-pentyl, n-hexyl, n-heptyl, n-octyl, and the like. An unsaturated alkyl group is one having one or more double bonds or triple bonds. Examples of unsaturated alkyl groups include, but are not limited to, vinyl, 2-propenyl, crotyl, 2-isopentenyl, 2-(butadienyl), 2,4-pentadienyl, 3-(1,4-pentadienyl), ethynyl, 1- and 3-propynyl, 3-butylnyl, and the higher homologs and isomers. Alkyl groups which are limited to hydrocarbon groups are termed "homoalkyl".

The term "alkylene" by itself or as part of another substituent means a divalent radical derived from an alkyl, as exemplified, but not limited, by -CH_2CH_2CH_2-, -CH_2CH=CHCH_2-, -CH_2C=CHCH_2-, and -CH_2CH=CHCH_2CH(CH_3)CH_2-. Typically, an alkyl (or alkylene) group will have from 1 to 24 carbon atoms, with those groups having 10 or fewer carbon atoms being preferred in the present invention. A "lower alkyl" or "lower alkylene" is a shorter chain alkyl or alkylene group, generally having eight or fewer carbon atoms.
The term "heteroalkyl," by itself or in combination with another term, means, unless otherwise stated, a stable straight or branched chain, or cyclic hydrocarbon radical, or combinations thereof, consisting of at least one carbon atom and at least one heteroatom selected from the group consisting of O, N, P, Si and S, and wherein the nitrogen, sulfur, and phosphorus atoms may optionally be oxidized and the nitrogen heteroatom may optionally be quaternized. The heteroatom(s) O, N, P and S and Si may be placed at any interior position of the heteroalkyl group or at the position at which alkyl group is attached to the remainder of the molecule.

Examples include, but are not limited to, -CH₂CH₂-O-CH₃, -CH₂CH₂-NH-CH₃, -CH₂CH₂-N(CH₃)₂-CH₃, -CH₂S-CH₂S₂CH₃, -CH₂CH₂-S(O)-CH₃, -CH₂CH₂Si(2)₂CH₃, -CH=CH-O-CH₃, -Si(CH₃)₃, -CH₂N(CH₃)-C₂H₅, O-CH₃, -O-CH₂CH₃ and -CN. Up to two or three heteroatoms may be consecutive, such as, for example, -CH₂-NH-OCH₃ and -CH₂-Si(CH₃)₃. Similarly, the term "heteroalkylene" by itself or as part of another substituent means a divalent radical derived from heteroalkyl, as exemplified, but not limited by, -CH₂CH₂-S-CH₂CH₂- and -CH₂S-S-CH₂CH₂-NH-CH₂-. For heteroalkylene groups, heteroatoms can also occupy either or both of the chain termini (e.g., alkenylenedioxo, alkenenamino, alkenediamino, and the like). Still further, for alkylene and heteroalkylene linking groups, no orientation of the linking group is implied by the direction in which the formula of the linking group is written. For example, the formula -C(O)OR' represents both -C(O)OR' and -R'OC(O)-. As described above, heteroalkyl groups, as used herein, include those groups that are attached to the remainder of the molecule through a heteroatom, such as -C(O)R', -C(O)NR', -NR'R", -OR', -SR', and/or -SO₂R'. Where "heteroalkyl" is recited, followed by recitations of specific heteroalkyl groups, such as -NRR" or the like, it will be understood that the terms heteroalkyl and -NRR" are not redundant or mutually exclusive. Rather, the specific heteroalkyl groups are recited to add clarity. Thus, the term "heteroalkyl" should not be interpreted herein as excluding specific heteroalkyl groups, such as -NRR" or the like.

The terms "cycloalkyl" and "heterocycloalkyl", by themselves or in combination with other terms, represent, unless otherwise stated, cyclic versions of "alkyl" and "heteroalkyl", respectively. Additionally, for heterocycloalkyl, a heteroatom can occupy the position at which the heterocycle is attached to the remainder of the molecule. Examples of cycloalkyl include, but are not limited to, cyclopentyl, cyclopentenyl, cyclohexyl, 1-cyclohexenyl, 3-cyclohexenyl, cycloheptyl, and the like. Examples of heterocycloalkyl include, but are not limited to, 1-(1,2,5,6-tetrahydropyridinyl), 1-piperidinyl, 2-piperidinyl, 3-piperidinyl, 4-morpholinyl, 3-morpholonyl, tetrahydrofuran-2-yl, tetrahydrofuran-3-yl, tetrahydrothien-2-yl, tetrahydrothien-3-yl, 1-piperazinyl, 2-piperazinyl, and the like. The terms "cycloalkylene" and "heterocycloalkylene" refer to the divalent derivatives of cycloalkyl and heterocycloalkyl, respectively.

The terms "halo" or "halogen," by themselves or as part of another substituent, mean, unless otherwise stated, a fluorine, chlorine, bromine, or iodine atom. Additionally, terms such as "haloalkyl," are meant to include monohaloalkyl and polyhaloalkyl. For example, the term "halo(C₃₋₅)alkyl" is mean to include, but not be limited to, trifluoromethyl, 2,2,2-trifluoroethyl, 4-chlorobutyl, 3-bromopropyl, and the like.

The term "aryl" means, unless otherwise stated, a polyunsaturated, aromatic, hydrocarbon substituent which can be a single ring or multiple rings (preferably from 1 to 3 rings) which are fused together or linked covalently. The term "heteroaryl" refers to aryl groups (or rings) that contain from one to four heteroatoms (in each separate ring in the case of multiple rings) selected from N, O, and S, wherein the nitrogen and sulfur atoms are optionally oxidized, and the nitrogen atom(s) are optionally quaternized. A heteroaryl group can be
attached to the remainder of the molecule through a carbon or heteroatom. Non-limiting examples of aryl and heteroaryl groups include phenyl, 1-naphthyl, 2-naphthyl, 4-biphenyl, 1-pyrryl, 2-pyrryl, 3-pyrryl, 3-pyrazolyl, 2-imidazolyl, pyrazinyl, 2-oxazolyl, 4-oxazolyl, 2-phenyl-4-oxazolyl, 5-oxazolyl, 3-isoxazolyl, 4-isoxazolyl, 5-isoxazolyl, 2-thiazolyl, 4-thiazolyl, 5-thiazolyl, 2-furyl, 3-furyl, 2-thienyl, 3-thienyl, 2-pyrindinyl, 3-pyrindinyl, 4-pyrimidinyl, 2-pyrimidinyl, 5-benzothiazolyl, purinyl, 2-benzimidazolyl, 5-indolyl, 1-isouquinolyl, 5-isouquinolyl, 2-quinoxalinyl, 3-quinolyl, and 6-quinolyl.

Also included in the definition of heteroaryl are N-oxide heteroaryl groups including but not limited to 2-pyridinyl N-oxide, 3-pyrindinyl N-oxide, 4-pyridinyl N-oxide, and the like.

Substituents for each of above noted aryl and heteroaryl ring systems are selected from the group of acceptable substituents described below. The terms "arylene" and "heteroarylene" refer to the divalent radicals of aryl and heteroaryl, respectively.

For brevity, the term "aryl" when used in combination with other terms (e.g., arylxoxo, arylthiooxo, arylalkyl) includes both aryl and heteroaryl rings as defined above. Thus, the term "arylalkyl" is meant to include those radicals in which an aryl group is attached to an alkyl group (e.g., benzyl, phenethyl, pyridinylmethyl and the like) including those alkyl groups in which a carbon atom (e.g., a methylene group) has been replaced by, for example, an oxygen atom (e.g., phenoxyethyl, 2-pyridinylmethoxymethyl, 3-(1-naphthoxy)propyl, and the like). However, the term "haloaryl," as used herein is meant to cover only aryls substituted with one or more halogens.

Where a heteroaryl, heterocycloalkyl, or heteroaryl includes a specific number of members (e.g. "3 to 7 membered"), the term "member" refers to a carbon or heteroatom.

The term "oxo" as used herein means an oxygen that is double bonded to a carbon atom.

Each of above terms (e.g., "alkyl," "heteroalkyl," "cycloalkyl, and "heterocycloalkyl," "aryl," "heteroaryl" as well as their divalent radical derivatives) are meant to include both substituted and unsubstituted forms of the indicated radical. Preferred substituents for each type of radical are provided below.

Substituents for alkyl, heteroalkyl, cycloalkyl, heterocycloalkyl monovalent and divalent derivative radicals (including those groups often referred to as alkylene, alkenyl, heteroalkylene, heteroalkenyl, alkynyl, cycloalkyl, heterocycloalkyl, cycloalkenyl, and heterocycloalkenyl) can be one or more of a variety of groups selected from, but not limited to: -OR', =O, =NR', =N-OR', =N'R'R", -SR', -halogen, -SiR'R"R'"", -OC(O)R', -C(O)R', -CO_2R', -C(O)NR'R"", -OC(O)NR'R"", -NR'C(O)R', -NR'-C(O)NR'R"", -NR'C(O)OR', -NR-C(NR'R"')=NR"", -S(O)R', -S(O)NR'R"", -S(O)NR'R"", -NRSO_2R', -CN and -NO_2 in a number ranging from zero to (2m'+1), where m' is the total number of carbon atoms in such radical. R', R", R''' and R''" each preferably independently refer to hydrogen, substituted or unsubstituted heteroalkyl, substituted or unsubstituted cycloalkyl, substituted or unsubstituted heterocycloalkyl, substituted or unsubstituted aryl (e.g., aryl substituted with 1-3 halogens), substituted or unsubstituted alkyl, alkoxy or thioalkoxy groups, or arylalkyl groups. When a compound of the invention includes more than one R group, for example, each of the R groups is independently selected as are each R', R", R''' and R"" groups when more than one of these groups is present. When R' and R" are attached to the same nitrogen atom, they can be combined with the nitrogen atom to form a 4-, 5-, 6-, or 7-membered ring. For example, -NR'R" is meant to include, but not be limited to, 1-pyrrolidinyl and 4-morpholinyl. From the above discussion of substituents, one of skill in the art will understand that the term
"alkyl" is meant to include groups including carbon atoms bound to groups other than hydrogen groups, such as haloalkyl (e.g., CF₃ and -CH₂CF₃) and acyl (e.g., -C(O)CH₃, -C(O)CF₃, -C(O)CH₂OCH₃, and the like).

Similar to the substituents described for alkyl radicals above, exemplary substituents for aryl and heteroaryl groups (as well as their divalent derivatives) are varied and are selected from, for example: halogen, -OR', -NR'R", -SR', -halogen, -SiR'R"=N=SiR'R", -OC(O)R', -C(O)R', -CO₂R', -C(O)NR'R", -OC(O)NR'R", -NR'C(O)R', -NR'-C(O)NR'R", -NR'-C(O)OR', -NR-C(NR'R'R")=NR", -NR-C(NR'R'R")=NR", -S(O)₂R', -S(O)₂N'R'R", -NR'S(O)₂R', -S(O)₂N'R'R", -NRS(O)₂R', -CN and -NO₂, -R', -N₃, -CH(Ph)₂, fluoro(C₁₋₃-C₄)alkoxy, and fluoro(C₁₋₃-C₄)alkyl, in a number ranging from zero to the total number of open valences on aromatic ring system; and where R', R", and R"" are preferably independently selected from hydrogen, substituted or unsubstituted alkyl, substituted or unsubstituted heteroalkyl, substituted or unsubstituted cycloalkyl, substituted or unsubstituted heterocycloalkyl, substituted or unsubstituted aryl and substituted or unsubstituted heteroaryl.

When a compound of the invention includes more than one R group, for example, each of the R groups is independently selected as are each R', R", and R"" groups when more than one of these groups is present.

Two of the substituents on adjacent atoms of aryl or heteroaryl ring may optionally form a ring of the formula -T-(C(O)-(CRR')ₜU⁻, wherein T and U are independently -NR-, -O-, -CRR'- or a single bond, and q is an integer of from 0 to 3. Alternatively, two of the substituents on adjacent atoms of aryl or heteroaryl ring may optionally be replaced with a substituent of the formula -A-(CH₂)ₐB-, wherein A and B are independently -CRR'-, -O-, -NR-, -S-, -S(O)ₐ, -S(O)₂ṣ, -S(O)₂N'R'- or a single bond, and r is an integer of from 1 to 4. One of the single bonds of the new ring so formed may optionally be replaced with a double bond. Alternatively, two of the substituents on adjacent atoms of aryl or heteroaryl ring may optionally be replaced with a substituent of the formula -C(RR')ₜ₁X'-(C'R'R'')ₜ₂, where s and d are independently integers of from 0 to 3, and X' is -O-, -NR', -S-, -S(O)₁, -S(O)₂, or -S(O)₂N'R'. The substituents R, R', R" and R"" are preferably independently selected from hydrogen, substituted or unsubstituted alkyl, substituted or unsubstituted cycloalkyl, substituted or unsubstituted heterocycloalkyl, substituted or unsubstituted aryl, and substituted or unsubstituted heteroaryl.

As used herein, the term "heteroatom" or "ring heteroatom" is meant to include oxygen (O), nitrogen (N), sulfur (S), phosphorus (P), and silicon (Si).

An "aminoalkyl" as used herein refers to an amino group covalently bound to an alkylene linker. The amino group is -NR'R", wherein R' and R" are typically selected from hydrogen, substituted or unsubstituted alkyl, substituted or unsubstituted heteroalkyl, substituted or unsubstituted cycloalkyl, substituted or unsubstituted heterocycloalkyl, substituted or unsubstituted aryl, or substituted or unsubstituted heteroaryl.

The compounds of the present invention may also contain unnatural proportions of atomic isotopes at one or more of atoms that constitute such compounds. For example, the compounds may be radiolabeled with radioactive isotopes, such as for example tritium (3H), iodine-125 (125I) or carbon-14 (14C). All isotopic variations of the compounds of the present invention, whether radioactive or not, are encompassed within the scope of the present invention.

The term "pharmacologically acceptable salts" is meant to include salts of active compounds which are prepared with relatively nontoxic acids or bases, depending on the particular substituent moieties found on the compounds described herein. When compounds of the present invention contain relatively acidic functionalities, base addition salts can be obtained by contacting the neutral form of such compounds with a sufficient amount of the desired base, either neat or in a suitable inert solvent. Examples of pharmaceutically
acceptable base addition salts include sodium, potassium, calcium, ammonium, organic amino, or magnesium salt, or a similar salt. When compounds of the present invention contain relatively basic functionalities, acid addition salts can be obtained by contacting the neutral form of such compounds with a sufficient amount of the desired acid, either neat or in a suitable inert solvent. Examples of pharmaceutically acceptable acid addition salts include those derived from inorganic acids like hydrochloric, hydrobromic, nitric, carbonic, monohydrogencarbonic, phosphoric, monohydrogenphosphoric, dihydrogenphosphoric, sulfuric, monohydrogensulfuric, hydriodic, or phosphorous acids and the like, as well as the salts derived from relatively nontoxic organic acids like acetic, propionic, isobutyric, maleic, malonic, benzoic, succinic, suberic, fumaric, lactic, mandelic, phthalic, benzenesulfonic, p-tolylsulfonic, citric, tartaric, methanesulfonic, and the like. Also included are salts of amino acids such as arginate and the like, and salts of organic acids like glucuronic or galactunoric acids and the like (see, for example, Berge et al., "Pharmaceutical Salts", Journal of Pharmaceutical Science, 1977, 66, 1-19). Certain specific compounds of the present invention contain both basic and acidic functionalities that allow the compounds to be converted into either base or acid addition salts.

In addition to salt forms, the present invention provides compounds, which are in a prodrug form. Prodrugs of the compounds described herein are those compounds that readily undergo chemical changes under physiological conditions to provide the compounds of the present invention. Additionally, prodrugs can be converted to the compounds of the present invention by chemical or biochemical methods in an ex vivo environment. For example, prodrugs can be slowly converted to the compounds of the present invention when placed in a transdermal patch reservoir with a suitable enzyme or chemical reagent.

The terms "a," "an," or "a(n)", when used in reference to a group of substituents herein, mean at least one. For example, where a compound is substituted with "an" alkyl or aryl, the compound is optionally substituted with at least one alkyl and/or at least one aryl. Moreover, where a moiety is substituted with an R substituent, the group may be referred to as "R-substituted." Where a moiety is R-substituted, the moiety is substituted with at least one R substituent and each R substituent is optionally different.

Description of compounds of the present invention are limited by principles of chemical bonding known to those skilled in the art. Accordingly, where a group may be substituted by one or more of a number of substituents, such substitutions are selected so as to comply with principles of chemical bonding and to give compounds which are not inherently unstable and/or would be known to one of ordinary skill in the art as likely to be unstable under ambient conditions, such as aqueous, neutral, and several known physiological conditions. For example, a heterocycloalyl or heteroaryl is attached to the remainder of the molecule via a ring heteroatom in compliance with principles of chemical bonding known to those skilled in the art thereby avoiding inherently unstable compounds.

The terms "treatment" or "treatment" in reference to a particular disease includes prevention of the disease.

The symbol \( \cdots \) denotes the point of attachment of a moiety to the remainder of the molecule.

**Exemplary Syntheses**

The compounds of the invention are synthesized by an appropriate combination of generally well known synthetic methods. Techniques useful in synthesizing the compounds of the invention are both readily apparent and accessible to those of skill in the relevant art. The discussion below is offered to illustrate how, in principle, to gain access to the compounds claimed under this invention and to give details on certain of the diverse methods available for use in assembling the compounds of the invention. However, the discussion is not intended to define or limit the scope of reactions or reaction sequences that are useful in preparing the compounds of the present invention. The compounds of this invention may be made by the procedures and
techniques disclosed in the Examples section below, as well as by known organic synthesis techniques. In Schemes 1, 2 and 3, L₁, R₁, L₂, and R₂ are as defined above.

The key intermediates for the synthesis of 3,5-disubstituted 1H-pyrazolo[3,4-b]pyridine derivatives are 5-bromo-1H-pyrazolo[3,4-b]pyridine and 5-bromo-3-iodo-1H-pyrazolo[3,4-b]pyridine. The iodine and/or bromine substituents on sp²-hybridized, aromatic carbon atoms present in these building blocks offer numerous synthetic possibilities for functionalization of either position. A great variety of such synthetic methods exists and these procedures are generally well known and familiar to someone with skill in the art and include, by means of example and not limitation: transition metal catalyzed processes, most notably processes utilizing palladium, iron, nickel or copper catalysts, as well as metal-halogen exchange reactions, most notably such procedures introducing lithium or magnesium, and subsequent reaction of the transient or isolated organometallic derivative with an electrophile of suitable reactivity either directly or via transmetallation to fine tune the reactivity of the organometallic species.

Using such methods, introduction of different substituents on the 3- and 5-position of the 1H-pyrazolo[3,4-b]pyridine core can be accomplished by introducing a chosen substituent at the 5-position starting from 5-bromo-1H-pyrazolo[3,4-b]pyridine and subsequent halogenation, especially iodination, at position 3 of the 1H-pyrazolo[3,4-b]pyridine core to enable the use of the aforementioned methods to introduce another substituent of choice at that position. Alternatively, some of the methods outlined above may be utilized to selectively functionalize 5-bromo-3-iodo-1H-pyrazolo[3,4-b]pyridine at the 3-position by selectively reacting with the iodo substituent over the bromo substituent. It is generally well known and familiar to someone with skill in the art, that a variety of palladium catalysts are known and readily available or accessible which will exhibit higher reaction rates with aromatic iodo substituents as compared to aromatic bromo substituents and such catalysts may be utilized under suitable conditions to effect selective iodine substitution.

5-bromo-1H-pyrazolo[3,4-b]pyridine or a derivative containing an appropriate protecting group may also be functionalized at the 3-position via various electrophilic aromatic substitution reactions that are generally well known and familiar to someone with skill in the art, such as FRIEDEL-CRAFTS-acylation.

The substituents introduced on either position in such fashion may either represent fully elaborated compounds, such as those claimed under this invention, or they may contain functional groups, such as, for example and without limitation, amines, carboxylic acids or esters, nitriles, olefins or halogens, either free or bearing suitable protecting groups, which in turn may be utilized as starting material in generally well known synthetic transformations to synthesize compounds that are claimed under this invention.

Suitably functionalized pyrazolo[3,4-b]pyridine derivatives, particularly 5-bromo-1H-pyrazolo[3,4-b]pyridine and 5-bromo-3-iodo-1H-pyrazolo[3,4-b]pyridine, useful in synthesizing compounds of the present invention can be prepared as outlined in Scheme 1 from commercially available 5-bromo-2-fluoropyridine and 5-Bromo-2-fluoropyridine can be selectively functionalized at the 3-position by the generally well known selective mettallation of 2-fluoropyridines in a manner resembling general methods described in Schlosser, M.,
The unpurified metallated intermediate can be converted to the corresponding 3-carbaldehyde 2 by treatment with a formylating reagent such as DMF, N-formyl-N-methylaniline, N-formylmorpholine, N-formylpiperidine or ethyl formate. Reaction of the carbaldehyde with hydrazine or a suitable hydrazine derivative (e.g. hydrazine-tert-butylcarbazate, or a soluble organic or inorganic salt derived from hydrazine such as hydrazine hydrochloride) either directly or upon protection of the aldehyde using a suitable protecting group (e.g. acetal) will provide access to 5-bromo-1H-pyrazolo[3,4-b]pyridine. Introduction of a suitable group at the 3-position for further elaboration can be accomplished via methods generally well known in the art, such as an electrophilic aromatic substitution (e.g. bromination or iodination). Thus, the iodide 4 is accessible from 3 by treatment with suitable reagents, such as N-iodosuccinimide, iodine monochloride or iodine, under conditions facilitating such transformation. Other examples of functionalization via electrophilic aromatic substitution are, by means of example and not limitation, FRIEDEL-CRAFTS-acylation using functionalized acyl halides such as, for example, bromoacetyl chloride, acryloyl chloride or trichloroacetyl chloride in the presence of aluminum trichloride in dichloromethane at ambient temperature or below. As will be appreciated by the skilled artisan, the products of such reactions may be utilized as starting materials for the synthesis of certain heterocyclic compounds.

Alternatively, the metallated intermediate derived from deprotonation of 5-bromo-2-fluoropyridine can be transmetallated under suitable conditions to form an organocuprate reagent (c.f. Lipshutz, B., Organometallics in Synthesis, 2nd ed., Wiley-VCH, 2002). Reaction of the cuprate generated in such fashion with an acyl halide gives access to ketones of the general structure 5, which can be cyclized by reaction with hydrazine or a soluble organic or inorganic salt derived from hydrazine (e.g. hydrazine hydrochloride) to afford the corresponding 3-substituted 5-bromo-1H-pyrazolo[3,4-b]pyridines of the general structure 6.

Other useful methods involve the conversion of a bromine or iodine substituent into a metal or metalloid substituent (e.g. organoboron, organolithium, organotin, organosilicon, organozinc, organocopper or organomagnesium compound) using generally well known methods (e.g. metal halogen exchange and, as appropriate or required, subsequent transmetallation using soluble and reactive compounds of boron, magnesium, zinc, tin, silicon or copper; for representative examples of such methodology see: Schlosser, M., *Organometallics in Synthesis*, 2nd. ed., Wiley-VCH, 2002.). Organometallic derivatives obtained in such fashion may itself be of use in transition metal catalyzed coupling reactions with aromatic or olefinic halides or triflates, or, if sufficiently reactive, be reacted directly with suitable electrophiles, such as, for example, certain organic halides, MICHAEL-acceptors, oxiranes, aziridines, aldehydes, acyl halides, or nitriles.

Selective functionalization at either the 3- or 5-position may require different strategies depending on the nature of the transformations utilized to introduce functionalities at either position, especially the sequence of functionalization at either position. Thus, it may be advantageous or necessary to achieve functionalization at the 3-position prior to functionalization of the 5-position in some cases while the opposite approach may be required in other cases, depending on the nature of the specific groups to be introduced, the methods required to accomplish such transformations, or the inherent selectivity of the methods utilized. For example, some reactants, such as for example some boronic acids or their esters that are electron deficient (e.g. contain one or more electron withdrawing substituents or that represent derivatives of certain heterocyclic systems) and/or contain one or more substituents ortho to the boron-carbon bond may require the use of highly active palladium catalysts (such as those mentioned in Vilar, R., Christman, U. (*Angew. Chem.* (2005) 117, 370; Littke, A.F., Fu, G. - *Angew. Chem.* (2002) 114, 4350) and more forcing conditions, such as higher temperatures and/or longer reaction times. Such conditions may not be conducive to achieving appreciable selectivities in reactions of 5-bromo-3-iodo-1H-pyrazolo[3,4- b]pyridine. Hence, in such cases, it may be advantageous to avoid selectivity issues altogether by sequential substitution of bromine in 5-bromo-1H-pyrazolo[3,4- b]pyridine, iodination at the 3-position and subsequent introduction of the second substituent at position 3 utilizing the methods detailed above. Generally, when substitution of the halogen atom at either position require conditions that involve highly reactive catalysts or reagents under conditions that generally do not favor high levels of selectivity between the two halogen atoms present in 5-bromo-3-iodo-1H-pyrazolo[3,4- b]pyridine, it may be advantageous to resort to this sequential approach.

It will also be appreciated that protection of reactive groups within L1, L2, R1 and/or R2 as well as the pyrazolo[3,4- b]pyridine scaffold, (e.g. the proton at position 1), with a suitable protecting group may be advantageous or required. For example it was found to be advantageous in some cross-coupling reactions to protect the nitrogen at position 1 of the 1H-pyrazolo[3,4- b]pyridine scaffold by introduction of either a (2trimethylsilylethoxy)-methyl or (2-methoxy-ethoxy)methyl group at that position. Introduction and removal of
these protecting groups could be conveniently accomplished by methods well known in the chemical literature. The compounds obtained by any of the aforementioned methods may contain functional groups, either free or protected, that can be further elaborated by generally well known methods.

A more detailed description of the utilization of cross-coupling procedures in the synthesis of the compounds claimed under this invention is illustrated in Scheme 2: $X^1$ and $X^2$ are selected from, but not limited to, halogen, boronic acid or ester, trifluoroborate salt, organomagnesium, organozinc, or organotin. With respect to the introduction of individual residues -L$^1$·R$^1$ or -L$^2$·R$^2$ such transformations, as outlined above, can be achieved via standard halogen cross-coupling methodologies.

Scheme 2

Couplings of the corresponding bromide or iodide ($X^1$, $X^2$ = Br, I) with suitable reagents such as boronic acids and boronates, organoboranes, organostannanes, organozinc compounds, organomagnesium compounds, olefins or terminal alkynes (either purchased or obtained via generally well known protocols) can be carried out in the presence of a suitable transition metal catalyst (e.g. palladium compounds). The coupling may optionally be performed in the presence of ligands such as phosphines, diphosphines, Arduengo-type heterocyclic carbenes or arsines. Organic or inorganic bases (e.g. tertiary or secondary amines, alkaline carbonates, bicarbonates or phosphate) and/or other well known additives (e.g. lithium chloride, copper halides or silver salts) may be utilized to assist or accelerate such transformations.

These cross coupling reactions may be carried out in suitable solvents such as THF, dioxane, dimethoxyethane, diglyme, dichloromethane, dichloroethane, acetonitrile, DMF, N-methylpyrrolidone, water, or mixtures thereof at temperatures ranging from 25°C to 200°C using. The temperature may optionally be maintained with heating, conventional heating or microwave irradiation. In the case of the 3-iodo-5-bromo-1H-pyrazolo[3,4-b]pyridine, the selective or preferential substitution of the iodo substituent over the bromo substituent is possible under generally less forcing conditions, such as lower temperature and shorter reaction times using a suitable transition metal catalyst. Selective functionalizations of di- or oligohalogen compounds by means of transition metal catalyzed transformations are well precededent in the chemical literature: see for example Ji, J., et al. Org.Lett (2003) 5, 461 1; Bach, T., et al., J.Org.Chem (2002) 67, 5789, Adamczyk, M. et.al., Tetrahedron (2003) 59, 8129.

This methodology may be extended to the incorporation of non-carbon based nucleophiles (e.g. alcohols, thiols, primary or secondary amines) that may optionally contain suitable protecting groups of

In some cases it may be advantageous to achieve cross-couplings to carbon or non-carbon atoms by first converting the respective halogen derivative into the corresponding organometallic derivative (e.g., a boronic acid or ester, trifluoroborate salt, organomagnesium, organozinc or organotin compound). Such compounds are accessible by means of substituting the halide moiety with an appropriate metal or metalloid. Any functional groups present (e.g., therethers nitrogen in position 1 of the pyrazolo[3,4-b]pyridine, may need to be protected by a suitable protecting group (“PG”). See Greene, et al., 1999.

Introduction of such metals or metalloids can be achieved by generally well-known methods, such as metallation using metals or a metal-halogen exchange reaction. Useful metals for metallation include alkaline or alkaline earth metals or activated forms of such metals. Suitable reagents for use in metal-halogen exchange reactions include organolithium or organomagnesium compounds (e.g., n-butyllithium, tert-butyllithium or iso-propylmagnesium chloride or bromide). Subsequent transmetalation reactions of the organometallic intermediate may be performed as needed with a suitable soluble and reactive metal compound such as magnesium chloride, magnesium bromide, tri-n-butyltin chloride, trimethyltin chloride, trimethyl borate, triethyl borate, tri-iso-propyl borate, zinc triflate or zinc chloride. Introduction of a boronic acid pinacol ester can be conveniently achieved by reacting the halogen derivative directly with bis(pinacolato)diboron in the presence of dichloro[1,1’-bis(diphenylphosphino)ferrocene]palladium(II) and suitable bases (e.g., potassium or sodium acetate) in solvents such as DMSO, DMF, DMA or N-methylpyrrolidone at temperatures ranging from 80-160°C. Conventional heating or microwave irradiation may be employed to maintain the appropriate temperature (for literature precedent of similar transformations, see Ishiyama, T., et al., *J. Org. Chem.* (1995) 60, 7508.)

Methods for conversion of the boronic acid pinacol ester obtained by this method into other boronic acid derivatives such as boronic acids, boronates, or trifluoroborate salts are generally well known. As will be apparent to the skilled artisan, such organometallic derivatives may be utilized in cross-coupling reactions similar to those described above in the case of halogen containing derivatives of pyrazolo[3,4-b]pyridine. Such couplings can be effected utilizing suitable coupling partners, such as aromatic, heteroaromatic halides or olefinic reagents under conditions identical or evidently similar and/or related to the methods described above.

Other methods may utilize the reactivity of organometallic derivatives generated from halogen containing derivatives of pyrazolo[3,4-b]pyridine by any of the methods described above. For example, derivatives containing alkaline or alkaline earth metals (e.g., organolithium, organomagnesium or organozinc compounds) may be employed in direct couplings to a range of other electrophilic coupling partners such as, for example, activated olefins (MICHAEL-acceptors), aldehydes, nitriles, aromatic nitro compounds, carboxylic acid derivatives, oxiranes, aziridines, organic disulfides or organic halides. Such transformations are generally well known in the art (for reactions with aromatic nitro compounds, see for example Sapountzis, I., et al., *J Am. Chem. Soc.* (2002) 124, 9390.).
The synthetic strategies utilized to access 3,5-disubstituted 1H-pyrrolo[2,3- \textit{b}]pyrazine derivatives are closely related to the strategies described above for 1H-pyrazolo[3,4- \textit{b}]pyridine derivatives, with the main difference relating to the synthesis of the 1H-pyrrolo[2,3- \textit{b}]pyrazine scaffold itself. The key intermediates utilized are 3-substituted 5-iodo-1H-pyrrolo[2,3- \textit{b}]pyrazine derivatives and 5-bromo-1H-pyrrolo[2,3- \textit{b}]pyrazine itself.

The general synthetic strategies to access 3,5-disubstituted 1H-pyrazolo[3,4- \textit{b}]pyridine derivatives from 5-bromo-1H-pyrazolo[3,4- \textit{b}]pyridine outlined above will also pertain to accessing 3,5-disubstituted 1H-pyrrolo[2,3- \textit{b}]pyrazine derivatives from 5-bromo-1H-pyrrolo[2,3- \textit{b}]pyrazine and 3-substituted 5-iodo-1H-pyrrolo[2,3- \textit{b}]pyrazine derivatives. However, the exact conditions for otherwise similar or identical transformations may very well be different for 1H-pyrrolo[2,3- \textit{b}]pyrazine derivatives and optimization depending on the scaffold utilized may be required.

5-Bromo-1H-pyrrolo[2,3- \textit{b}]pyrazine is accessible via regioselective SONOGASHIRA-coupling of 3-amino-2,6-dibromo-pyrazine with trimethylsilylacetylene (see Adamczyk,M., et al. - \textit{Tetrahedron} (2003) 59, 8129.), N-acylation, and subsequent cyclization using -\textit{n}-butylammonium fluoride (for precedent of this reaction please see WO2004/032874A2). Starting from commercially available 3-amino-2,6-dibromo-pyrazine, 5-bromo-3-trimethylsilylthethyl-pyrazin-2-ylamine can be obtained by reaction with trimethylsilylacetylene in the presence of a palladium catalyst, such as tetrakis(triphenylphosphino) palladoid(0) and a catalytic amount of a copper co-catalyst, such as copper(i)-iodide in a mixture of DMF and a basic tertiary organic amine, such as triethylamine at elevated temperatures. Acetylation with acetyl chloride in pyridine at 20-60 °C gives access to N-(5-bromo-3-trimethylsilylthethyl-pyrazin-2-yl)-acetamide and subsequent cyclization with tetra-\textit{n}-butylammonium fluoride in THF under reflux affords 5-bromo-1H-pyrrolo[2,3- \textit{b}]pyrazine.

Introduction of a suitable group at the 3-position for further elaboration can be accomplished via methods generally well known in the art, such as an electrophilic aromatic substitution (e.g. bromination or iodination). Thus, 5-bromo-3-iodo-1H-pyrrolo[2,3- \textit{b}]pyrazine is accessible from 5-bromo-1H-pyrrolo[2,3- \textit{b}]pyrazine by treatment with suitable reagents, such as N-iodosuccinimide, iodine monochloride or iodine, under conditions facilitating such transformation.

Other examples of functionalization via electrophilic aromatic substitution are, by means of example and not limitation, FRIEDEL-CRAFTS-acylation using functionalized acyl halides such as, for example, bromoacetyl chloride, acryloyl chloride or trichloroacetyl chloride in the presence of aluminum trichloride in dichloromathane at ambient temperature or below. As will be appreciated by the skilled artisan, the products of such reactions either represent compounds claimed under this invention or may be utilized as starting materials for the synthesis of such compounds, most notably certain heterocyclic compounds.

Further elaboration of halide D (X=Br, I) as well as selective sequential substitution of both halogen substituents in 5-bromo-3-iodo-1H-pyrrolo[2,3- \textit{b}]pyrazine can be readily accomplished by generally well known methods, such as, for example, sequential metal catalyzed cross coupling reactions may be employed using various known transition metal compounds (e.g. compounds derived from palladium, iron or nickel).

The general methods known in the chemical literature and familiar to someone with skill in the art are essentially the same methods as those described above for similar or identical transformations utilizing 1H-pyrazolo[3,4-b]pyridine derivatives.

As was discussed for 1H-pyrazolo[3,4-b]pyridines the skilled artisan will appreciate that selective functionalization at either the 3- or 5-position may require different strategies depending on the nature of the transformations utilized to introduce functionalities at either position, especially the sequence of functionalization at either position. Thus, it may be advantageous or necessary to achieve functionalization at the 3-position prior to functionalization of the 5-position in some cases while the opposite approach may be required in other cases, depending on the nature of the specific groups to be introduced, the methods required to accomplish such transformations, or the inherent selectivity of the methods utilized.

In the case of the 3-iodo-5-bromo-1H-pyrazolo[2,3-b]pyrazine, the selective or preferential substitution of the iodo substituent over the bromo substituent is possible under generally less forcing conditions, such as lower temperature and shorter reaction times using a suitable transition metal catalyst. Selective functionalizations of di- or oligohalogen compounds by means of transition metal catalyzed transformations are well preceded in the chemical literature: see for example Ji, J., et al. Org.Lett (2003) 5, 4611; Bach, T., et al., J.Org.Chem (2002) 67, 5789, Adamczyk, M. et al., Tetrahedron (2003) 59, 8129.

In the case of halide D (X=Br, I) other useful methods may involve the conversion of a bromine or iodine substituent into a metal or metalloid substituent (e.g. organoboron, organothium, organotin, organosilicon, organozinc, organocopper or organomagnesium compound) using generally well known methods (e.g. metal halogen exchange and, as appropriate or required, subsequent transmetallation using soluble and reactive compounds of boron, magnesium, zinc, tin, silicon or copper; for representative examples of such methodology see: Schlosser, M., Organometallics in Synthesis, 2nd ed., Wiley-VCH, 2002). Organometallic derivatives obtained in such fashion may itself be of use in transition metal catalyzed coupling reactions with aromatic or olefinic halides or triflates, or, if sufficiently reactive, be reacted directly with suitable electrophiles, such as, for example, certain organic halides, MICHAEL-acceptors, oxiranes, aziridines, aldehydes, acyl halides, or nitriles. Again, the general methods known in the chemical literature are essentially the same as those described above for similar or identical transformations utilizing 1H-pyrazolo[3,4-b]pyridine derivatives.

In certain such transformations, it may be advantageous or required to introduce one or more suitable protecting groups, in order to temporarily substitute acidic protons, such as, for example, the hydrogen atoms attached to nitrogen or oxygen, as needed, and in particular the hydrogen atom in position 1 of the 1H-pyrazolo[2,3-b]pyrazine scaffold, by methods well known in the chemical literature (cf. T.W.Greene, P.G.M.Wuts - Protective Groups in Organic Synthesis, 3rd ed., John Wiley & Sons, 1999).

The cross-coupling methodology described above may be extended to the incorporation of non-carbon based nucleophiles (e.g. alcohols, thiols, primary or secondary amines) that may optionally contain suitable protecting groups of alcohols, thiols or amines. Examples of such groups can be found in Greene, T., et al., Protective Groups in Organic Synthesis, 3rd ed., John Wiley & Sons, 1999. Exemplary methods of
protection are described in Ley, S., et al., Angew.Chem. (2003) 115, 5558; Wolfe, J., et al., Acc. Chem.Res. (1998) 31, 805; Hartwig, Acc.Chem.Res. (1998) 31, 852; Navarro, O., et al. J.Org.Chem. (2004) 69, 3173, Ji, J., et al., Org.Lett (2003) 5, 461. The compounds obtained by such methods can be further elaborated by well known methods to obtain other compounds of the present invention. In some cases, direct substitution of the 5-iodo or 5-bromo substituent in 1H-pyrrolo[2,3-b]pyrazine with an amine, alcohol or thiol may be successfully accomplished at ambient or elevated temperatures in the presence of weak acids, such as, for example, acetic acid, or a strong, non-nucleophilic base, such as, for example, sodium hydride either in neat amine, alcohol or thiol, respectively or in a suitable aprotic solvent, such as, for example, DMF, NMP, DMSO, or acetonitrile.

Scheme 3

An alternative method for the synthesis of 3,5-disubstituted 1H-pyrrolo[2,3-b]pyrazine derivatives was developed, starting from methyl 2-amino-3-pyrazinecarboxylate, incorporation of an iodine atom on the 5-position to give methyl 2-amino-5-iodo-3-pyrazinecarboxylate can be achieved by various known methods, such as reaction with N-iodosuccinimide in ethanol at reflux. The halogenated ester obtained by such means may then be hydrolyzed by standard methods. For example, treatment with lithium hydroxide in THF-water mixtures at ambient temperature affords the corresponding acid.

Synthesis of a ketone intermediate B can be achieved by treating the corresponding WEINREB-amide A (3-amino-6-ido-pyrazine-2-carboxylic acid methoxy-methyl-amide) or its hydrochloride salt with a suitable organometallic species, for example, using an organomagnesium or organolithium compound. (For examples of
the use of N-methoxy-N-methylamides (Weinreb Amides) in ketone synthesis, see S.Nam, S.M. Weinreb -
Tetrahedron Lett. 1981, 22,3815.) 3-Amino-6-iodo-pyrazine-2-carboxylic acid methoxy-methyl-amine (A) is
accessible by condensation of the parent acid with N,O-dimethylhydroxylamine using standard methods for
amide-formation, either by prior activation of the acid or in situ or via direct condensation. Methods and
reagents for both transformations are described in the chemical literature and well known to someone skilled in
the art, such as in the case of direct methods using suitable coupling reagents such as, but not limited to, PyBOP,
HBTU or HATU.

The organometallic reagents required for the introduction of a ketone residue L-R1 in B can be
obtained either commercially or synthesized by various methods described in the literature, such as, but not
limited to the GRIGNARD-reaction of organic chlorides, bromides, or iodides, with magnesium (cf. J. March -
bromides or iodides using suitable organolithium or organomagnesium compounds such as, but not limited to, n-
butyllithium, tert-butyllithium or iso-propylmagnesium chloride or bromide (e.g. J.Clayden - Organolithiums: Selectivity for
Synthesis, Pergamon, 2002; A.Boudier, L.O.Bromm, M.Lotz, P.Knochel- Angew. Chem. Int. Ed. (2000) 39, 4414.) or depromotion of sufficiently acidic compounds, such as for example pyrimidines,
pyrazines, 2-chloro- or 2-fluoropyridines using a suitable base, such as for example lithium N,N-
diisopropylamid or lithium 2,2,6,6-tetramethylpiperidide (cf. J.Clayden - Organolithiums: Selectivity for
G.Quéguiner - Tetrahedron (2001) 57,4059). In certain such transformations, it may be advantageous or
required to introduce one or more suitable protecting groups, in order to temporarily substitute acidic protons
(e.g. the hydrogen atoms attached to nitrogen or oxygen) as needed, by methods well known in the chemical
1999).

Conversion of the ketone intermediate B to the methoxyvinyl derivative C can be achieved by
several known methods but is most conveniently carried out via a WITTIG-reaction (cf. B.E.Maryanoff,
methoxymethyltriphenylphosphonium chloride and a suitable base, for example, but not limited to, a strong
organometallic base such as, but not limited to, a non-nucleophilic amide such as the lithium, sodium or
potassium salt of bis(trimethylsilyl)amine.

Subsequent cyclization of the resulting olefin C, which can be utilized in either the E- or Z-form or a
mixture of these both forms, can be achieved under general acid catalysis conditions to afford 3-substituted 1H-
5-iodo-pyrrolo[2,3-b]pyrazines. Such methods may utilize strong inorganic or organic acids, such as sulfuric
acid, perchloric acid, hydrochloric acid, trifluoromethanesulfonic acid or trifluoroacetic acid in suitable solvents
(e.g. THF, dioxane, diethyl ether, dimethoxyethane, diglyme, dichloromethane, dichloroethane or chloroform,
water, methanol, or ethanol, or mixtures thereof) at temperatures ranging from 0°C to 160°C. A similar
cyclization has been described by Sakamoto et al., Heterocycles (1992), 34(12), 2379-84. There the authors
describe the conversion of 2-nitro-3-(2-ethoxyvinyl)pyridine to the parent pyrrolo[2,3-b]pyridine. Formation of
the vinyl group was reported to be achieved via a STILLE-coupling of the 3-bromo analog with tributyl-2-
ethoxyvinylstannane.
The utility of 3-substituted 1H-5-iodo-pyrrolo[2,3-b]pyrazines in the synthesis of compounds claimed under this invention will be obvious to someone skilled in the art based on the methods described above. One of skill will immediately understand that the synthetic methods described herein, including the Examples section below, may be used and/or elaborated to obtain the compounds of Formulae (I), (II), and/or (III).

**Protecting Groups**

The term "protecting group" refers to chemical moieties that block some or all reactive moiety of a compound and prevent such moieties from participating in chemical reactions until the protective group is removed, for example, those moieties listed and described in T.W. Greene, P.G.M. Wuts, Protective Groups in Organic Synthesis, 3rd ed. John Wiley & Sons (1999). It may be advantageous, where different protecting groups are employed, that each (different) protective group be removable by a different means. Protective groups that are cleaved under totally disparate reaction conditions allow differential removal of such protecting groups. For example, protective groups can be removed by acid, base, and hydrogenolysis. Groups such as trityl, dimethoxytrityl, acetal and tert-butylidimethylsilyl are acid labile and may be used to protect carboxy and hydroxy reactive moieties in the presence of amino groups protected with Cbz groups, which are removable by hydrogenolysis, and Fmoc groups, which are base labile. Carboxylic acid and hydroxy reactive moieties may be blocked with base labile groups such as, without limitation, methyl, ethyl, and acetyl in the presence of amines blocked with acid labile groups such as tert-butyl carbamate or with carbamates that are both acid and base stable but hydrolytically removable.

Carboxylic acid and hydroxy reactive moieties may also be blocked with hydrolytically removable protective groups such as the benzyl group, while amine groups capable of hydrogen bonding with acids may be blocked with base labile groups such as Fmoc. Carboxylic acid reactive moieties may be blocked with oxidatively-removable protective groups such as 2,4-dimethoxybenzyl, while co-existing amino groups may be blocked with fluoride labile silyl carbamates.

Allyl blocking groups are useful in the presence of acid- and base-protecting groups since the former are stable and can be subsequently removed by metal or p-lid acid catalysts. For example, an allyl-blocked carboxylic acid can be deprotected with a palladium(0)-catalyzed reaction in the presence of acid labile t-butyl carbamate or base-labile acetate amine protecting groups. Yet another form of protecting group is a resm to which a compound or intermediate may be attached. As long as the residue is attached to the resin, that functional group is blocked and cannot react. Once released from the resin, the functional group is available to react.

Typical blocking/protecting groups include, but are not limited to the following moieties:
Methods of Inhibiting Kinases

In another aspect, the present invention provides methods of modulating protein kinase activity using the fused ring heterocycle kinase modulators of the present invention. The term "modulating kinase activity," as used herein, means that the activity of the protein kinase is increased or decreased when contacted with a fused ring heterocycle kinase modulator of the present invention relative to the activity in the absence of the fused ring heterocycle kinase modulator. Therefore, the present invention provides a method of modulating protein kinase activity by contacting the protein kinase with a fused ring heterocycle kinase modulator of the present invention (e.g. the compounds of any one of Formulae (I)-(III)).

In an exemplary embodiment, the fused ring heterocycle kinase modulator inhibits kinase activity. The term "inhibit," as used herein in reference to kinase activity, means that the kinase activity is decreased when contacted with a fused ring heterocycle kinase modulator relative to the activity in the absence of the fused ring heterocycle kinase modulator. Therefore, the present invention further provides a method of inhibiting protein kinase activity by contacting the protein kinase with a fused ring heterocycle kinase modulator of the present invention.

In certain embodiments, the protein kinase is a protein tyrosine kinase. A protein tyrosine kinase, as used herein, refers to an enzyme that catalyzes the phosphorylation of tyrosine residues in proteins with a phosphate donors (e.g. a nucleotide phosphate donor such as ATP). Protein tyrosine kinases include, for example, Abelson tyrosine kinases ("Abl") (e.g. c-Abl and v-Abl), Ron receptor tyrosine kinases ("RON"), Met receptor tyrosine kinases ("MET"), Fms-like tyrosine kinases ("FLT") (e.g. FLT3), src-family tyrosine kinases (e.g. lyn, CSK), and p21-activated kinase-4 ("PAK"), FLT3, aurora kinases, B-lymphoid tyrosine kinases ("Blk"), cyclin-dependent kinases ("CDK") (e.g. CDKland CDK5), src-family related protein tyrosine kinases (e.g. Fyn kinase), glycogen synthase kinases ("GSK") (e.g. GSK3α and GSK3β), lymphocyte protein tyrosine kinases ("Lck"), ribosomal S6 kinases (e.g. Rsk1, Rsk2, and Rsk3), sperm tyrosine kinases (e.g. Yes), and subtypes and homologs thereof exhibiting tyrosine kinase activity. In certain embodiments, the protein tyrosine
kinase is Abl, RON, MET, PAK, or FLT3. In other embodiments, the protein tyrosine kinase is a FLT3 or Abl family member.

In some embodiments, the kinase is selected from Abelson tyrosine kinase, Ron receptor tyrosine kinase, Met receptor tyrosine kinase, Fms-like tyrosine kinase-3, Aurora kinases, p21-activated kinase-4, and 3-phosphoinositide-dependent kinase-1.

In another embodiment, the kinase is a mutant kinase, such as a mutant Bcr-Abl kinase, FLT3 kinase or aurora kinases. Useful mutant Bcr-Abl kinases include those having at least one of the following clinically isolated mutations: M244V, L248V, G250E, G250A, Q252H, Q252R, Y253F, Y253H, E255K, E255V, D276G, F311L, T315I, T315N, T315A, F317V, F317L, M343T, M351T, E355G, F359A, F359V, V379I, F382L, L387M, H396F, H396R, S417Y, E459K and F486S. In some embodiments, the mutant Abl kinase has a T315I mutation. The numbering system denoting the position of the amino acid mutation above the well known wild-type ABL numbering according to ABL exon Ia. See Deininger, M., et al., Blood 105(7), 2640 (2005). The numbering system is reproduced in Figure 1. In some embodiments, the mutant Bcr-Abl kinase includes at least one of the mutations listed above and has at least 80%, 85%, 90%, 95%, 96%, 97%, 98%, or 100% sequence identity to the sequence of Figure 1 (SEQ ID NO: 23).

In some embodiments, the mutant Bcr-Abl kinase includes at least one of the mutations listed above, has a sequence identity to Figure 1 as discussed above, and includes at least 50, 100, 150, 200, 250, 300, 350, 400, 450, 500, 550, 600, 650, 700, 750, 800, 850, 900, 950, 1000, 1050, or 1100 amino acids.

In some embodiments, the kinase is homologous to a known kinase (also referred to herein as a "homologous kinase"). Compounds and compositions useful for inhibiting the biological activity of homologous kinases maybe initially screened, for example, in binding assays. Homologous enzymes comprise an amino acid sequence of the same length that is at least 50%, at least 60%, at least 70%, at least 80%, or at least 90% identical to the amino acid sequence of full length known kinase, or 70%, 80%, or 90% homology to the known kinase active domains. Homology may be determined using, for example, a PSI BLAST search, such as, but not limited to that described in Altschul, et al., Nuc. Acids Rec, 25:3389-3402 (1997). In certain embodiments, at least 50%, or at least 70% of the sequence is aligned in this analysis. Other tools for performing the alignment include, for example, DBClustal and ESPript, which may be used to generate the PostScript version of the alignment. See Thompson et al., Nucleic Acids Research, 28:2919-26, 2000; Gouet, et al., Bioinformatics, 15:305-08 (1999). Homologs may, for example, have a BLAST E-value of 1 x 10^-6 over at least 100 amino acids (Altschul et al., Nucleic Acids Res., 25:3389-402 (1997) with FLT3, Abl, or another known kinase, or any functional domain of FLT3, Abl, or another known kinase.

Homology may also be determined by comparing the active site binding pocket of the enzyme with the active site binding pockets of a known kinase. For example, in homologous enzymes, at least 50%, 60%, 70%, 80%, or 90% of the amino acids of the molecule or homolog have amino acid structural coordinates of a domain comparable in size to the kinase domain that have a root mean square deviation of the alpha carbon atoms of up to about 1.5Å, about 1.25Å, about 1Å, about 0.75Å, about 0.5Å, and or about 0.25Å.

The compounds and compositions of the present invention are useful for inhibiting kinase activity and also for inhibiting other enzymes that bind ATP. They are thus useful for the treatment of diseases and disorders that may be alleviated by inhibiting such ATP-binding enzyme activity. Methods of determining such ATP binding enzymes include those known to those of skill in the art, those discussed herein relating to
selecting homologous enzymes, and by the use of the database PROSITE, where enzymes containing signatures, sequence patterns, motifs, or profiles of protein families or domains may be identified.

The compounds of the present invention, and then: derivatives, may also be used as kinase-binding agents. As binding agents, such compounds and derivatives may be bound to a stable resin as a tethered substrate for affinity chromatography applications. The compounds of this invention, and their derivatives, may also be modified (e.g., radiolabeled or affinity labeled, etc.) in order to utilize them in the investigation of enzyme or polypeptide characterization, structure, and/or function.

In an exemplary embodiment, the fused ring heterocycle kinase modulator of the present invention is a kinase inhibitor. In some embodiments, the kinase inhibitor has an IC₅₀ of inhibition constant (Kᵢ) of less than 1 micromolar. In another embodiment, the kinase inhibitor has an IC₅₀ or inhibition constant (Kᵢ) of less than 500 micromolar. In another embodiment, the kinase inhibitor has an IC₅₀ or Kᵢ of less than 10 micromolar. In another embodiment, the kinase inhibitor has an IC₅₀ or Kᵢ of less than 1 micromolar. In another embodiment, the kinase inhibitor has an IC₅₀ or Kᵢ of less than 500 nanomolar. In another embodiment, the kinase inhibitor has an IC₅₀ or Kᵢ of less than 10 nanomolar. In another embodiment, the kinase inhibitor has an IC₅₀ or Kᵢ of less than 1 nanomolar.

**Methods of Treatment**

In another aspect, the present invention provides methods of treating a disease mediated by kinase activity (kinase-mediated disease or disorder) in an organism (e.g. mammals, such as humans). By "kinase-mediated" or "kinase-associated" diseases is meant diseases in which the disease or symptom can be alleviated by inhibiting kinase activity (e.g. where the kinase is involved in signaling, mediation, modulation, or regulation of the disease process). By "diseases" is meant diseases, or disease symptoms. The method includes administering to the subject an effective amount of a fused ring heterocycle kinase modulator of the present invention (e.g. the compounds of any one of Formulae (I)-(III)).

Examples of kinase associated diseases include cancer (e.g. leukemia, tumors, and metastases), allergy, asthma, obesity, inflammation (e.g. inflammatory diseases such as inflammatory airways disease), hematological disorders, obstructive airways disease, asthma, autoimmune diseases, metabolic diseases, infection (e.g. bacterial, viral, yeast, fungal), CNS diseases, brain tumors, degenerative neural diseases, cardiovascular diseases, and diseases associated with angiogenesis, neovascularization, and vasculogenesis. In an exemplary embodiment, the compounds are useful for treating cancer, including leukemia, and other diseases or disorders involving abnormal cell proliferation, such as myeloproliferative disorders.

More specific examples of cancers treated with the compounds of the present invention include breast cancer, lung cancer, melanoma, colorectal cancer, bladder cancer, ovarian cancer, prostate cancer, renal cancer, squamous cell cancer, glioblastoma, pancreatic cancer, Kaposi's sarcoma, multiple myeloma, and leukemia (e.g. myeloid, chronic myeloid, acute lymphoblastic, chronic lymphoblastic, Hodgkin's, and other leukemias and hematological cancers).

Other specific examples of diseases or disorders for which treatment by the compounds or compositions of the invention are useful for treatment or prevention include, but are not limited to transplant rejection (for example, kidney, liver, heart, lung, islet cells, pancreas, bone marrow, cornea, small bowel, skin allografts or xenografts and other transplants), graft vs. host disease, osteoarthritis, rheumatoid arthritis, multiple sclerosis, diabetes, diabetic retinopathy, inflammatory bowel disease (for example, Crohn's disease, ulcerative

**Assays**

The compounds of the present invention may be easily assayed to determine their ability to modulate protein kinases, bind protein kinases, and/or prevent cell growth or proliferation. Some examples of useful assays are presented below.

**Kinase Inhibition and Binding Assays**

Inhibition of various kinases is measured by methods known to those of ordinary skill in the art, such as the various methods presented herein, and those discussed in the Upstate KinaseProfiler Assay Protocols June 2003 publication.

For example, where *in vitro* assays are performed, the kinase is typically diluted to the appropriate concentration to form a kinase solution. A kinase substrate and phosphate donor, such as ATP, is added to the kinase solution. The kinase is allowed to transfer a phosphate to the kinase substrate to form a phosphorylated substrate. The formation of a phosphorylated substrate may be detected directly by any appropriate means, such as radioactivity (e.g. $^{32}$P-ATP), or the use of detectable secondary antibodies (e.g. ELISA). Alternatively, the formation of a phosphorylated substrate may be detected using any appropriate technique, such as the detection of ATP concentration (e.g. Kinase-Glo® assay system (Promega)). Kinase inhibitors are identified by detecting the formation of a phosphorylated substrate in the presence and absence of a test compound (see Examples section below).

The ability of the compound to inhibit a kinase in a cell may also be assayed using methods well known in the art. For example, cells containing a kinase may be contacted with an activating agent (such as a growth factor) that activates the kinase. The amount of intracellular phosphorylated substrate formed in the absence and the presence of the test compound may be determined by lysing the cells and detecting the presence phosphorylated substrate by any appropriate method (e.g. ELISA). Where the amount of phosphorylated substrate produced in the presence of the test compound is decreased relative to the amount produced in the absence of the test compound, kinase inhibition is indicated. More detailed cellular kinase assays are discussed in the Examples section below.

To measure the binding of a compound to a kinase, any method known to those of ordinary skill in the art may be used. For example, a test kit manufactured by Discoverx (Fremont, CA), ED-Staurosporine NSIP™ Enzyme Binding Assay Kit (see U.S. Patent No. 5,643,734) may be used. Kinase activity may also be assayed as in U.S. Patent 6,589,950, issued July 8, 2003. Suitable kinase inhibitors may be selected from the compounds of the invention through protein crystallographic screening, as disclosed in, for example Antonyssamy, et al., PCT Publication No. WO03087816A1, which is incorporate herein by reference in its entirety for all purposes.

The compounds of the present invention may be computationally screened to assay and visualize their ability to bind to and/or inhibit various kinases. The structure may be computationally screened with a
plurality of compounds of the present invention to determine their ability to bind to a kinase at various sites. Such compounds can be used as targets or leads in medicinal chemistry efforts to identify, for example, inhibitors of potential therapeutic importance (Travis, Science, 262:1374, 1993). The three dimensional structures of such compounds may be superimposed on a three dimensional representation of kinases or an active site or binding pocket thereof to assess whether the compound fits spatially into the representation and hence the protein. In this screening, the quality of fit of such entities or compounds to the binding pocket may be judged either by shape complementarity or by estimated interaction energy (Meng, et al., J. Comp. Chem., 13:505-24, 1992).

The screening of compounds of the present invention that bind to and/or modulate kinases (e.g. inhibit or activate kinases) according to this invention generally involves consideration of two factors. First, the compound must be capable of physically and structurally associating, either covalently or non-covalently with kinases. For example, covalent interactions may be important for designing irreversible or suicide inhibitors of a protein. Non-covalent molecular interactions important in the association of kinases with the compound include hydrogen bonding, ionic interactions, van der Waals, and hydrophobic interactions. Second, the compound must be able to assume a conformation and orientation in relation to the binding pocket, that allows it to associate with kinases. Although certain portions of the compound will not directly participate in this association with kinases, those portions may still influence the overall conformation of the molecule and may have a significant impact on potency. Conformational requirements include the overall three-dimensional structure and orientation of the chemical group or compound in relation to all or a portion of the binding pocket, or the spacing between functional groups of a compound comprising several chemical groups that directly interact with kinases.

Docking programs described herein, such as, for example, DOCK, or GOLD, are used to identify compounds that bind to the active site and/or binding pocket. Compounds may be screened against more than one binding pocket of the protein structure, or more than one set of coordinates for the same protein, taking into account different molecular dynamic conformations of the protein. Consensus scoring may then be used to identify the compounds that are the best fit for the protein (Charifson, P.S. et al., J Med Chem., 42: 5100-9 (1999)). Data obtained from more than one protein molecule structure may also be scored according to the methods described in Klingler et al., U.S. Utility Application, filed May 3, 2002, entitled "Computer Systems and Methods for Virtual Screening of Compounds." Compounds having the best fit are then obtained from the producer of the chemical library, or synthesized, and used in binding assays and bioassays.

Computer modeling techniques may be used to assess the potential modulating or binding effect of a chemical compound on kinases. If computer modeling indicates a strong interaction, the molecule may then be synthesized and tested for its ability to bind to kinases and affect (by inhibiting or activating) its activity.

Modulating or other binding compounds of kinases may be computationally evaluated by means of a series of steps in which chemical groups or fragments are screened and selected for their ability to associate with the individual binding pockets or other areas of kinases. This process may begin by visual inspection of, for example, the active site on the computer screen based on the kinases coordinates, Selected fragments or chemical groups may then be positioned in a variety of orientations, or docked, within an individual binding pocket of kinases (Blaney, J.M. and Dixon, J.S., Perspectives in Drug Discovery and Design, 1:301, 1993).

Manual docking may be accomplished using software such as Insight II (Accelrys, San Diego, CA) MOE
(Chemical Computing Group, Inc., Montreal, Quebec, Canada); and SYBYL (Tripos, Inc., St. Louis, MO, 1992), followed by energy minimization and/or molecular dynamics with standard molecular mechanics force fields, such as CHARMM (Brooks, et al., J. Comp. Chem. 4:187-217, 1983), AMBER (Weiner, et al., J. Am. Chem. Soc., 106: 765-84, 1984) and C2-MMFF (Merck Molecular Force Field; Accelrys, San Diego, CA). More automated docking may be accomplished by using programs such as DOCK (Kuntz et al., J. Mol. Biol., 161:269-88, 1982; DOCK is available from University of California, San Francisco, CA); AUTODOCK (Goodsell & Olsen, Proteins: Structure, Function, and Genetics 8:195-202, 1990; AUTODOCK is available from Scripps Research Institute, La Jolla, CA); GOLD (Cambridge Crystallographic Data Centre (CCDC); Jones et al., J. Mol. Biol., 245:43-53, 1995); and FLEXX (Tripos, St Louis, MO; Rarey, M., et al., J. Mol. Biol., 261:470-89, 1996). Other appropriate programs are described in, for example, Harperin, et al.

During selection of compounds by the above methods, the efficiency with which that compound may bind to kinases may be tested and optimized by computational evaluation. For example, a compound that has been designed or selected to function as a kinases inhibitor may occupy a volume not overlapping the volume occupied by the active site residues when the native substrate is bound, however, those of ordinary skill in the art will recognize that there is some flexibility, allowing for rearrangement of the main chains and the side chains. In addition, one of ordinary skill may design compounds that could exploit protein rearrangement upon binding, such as, for example, resulting in an induced fit. An effective kinase inhibitor may demonstrate a relatively small difference in energy between its bound and free states (i.e., it must have a small deformation energy of binding and/or low conformational strain upon binding). Thus, the most efficient kinase inhibitors should, for example, be designed with a deformation energy of binding of not greater than 10 kcal/mol, not greater than 7 kcal/mol, not greater than 5 kcal/mol, or not greater than 2 kcal/mol. Kinase inhibitors may interact with the protein in more than one conformation that is similar in overall binding energy. In those cases, the deformation energy of binding is taken to be the difference between the energy of the free compound and the average energy of the conformations observed when the inhibitor binds to the enzyme.

Specific computer software is available in the art to evaluate compound deformation energy and electrostatic interaction. Examples of programs designed for such uses include: Gaussian 94, revision C (Frisch, Gaussian, Inc., Pittsburgh, PA, ©1995); AMBER, version 7. (Kollman, University of California at San Francisco, ©2002); QUANTA/CHARMM (Accelrys, Inc., San Diego, CA, ©1995); Insight II/Discover (Accelrys, Inc., San Diego, CA, ©1995); DelPhi (Accelrys, Inc., San Diego, CA, ©1995); and AMSOL (University of Minnesota) (Quantum Chemistry Program Exchange, Indiana University). These programs may be implemented, for instance, using a computer workstation, as are well known in the art, for example, a LINUX, SGI or Sun workstation. Other hardware systems and software packages will be known to those skilled in the art.

Those of ordinary skill in the art may express kinase protein using methods known in the art, and the methods disclosed herein. The native and mutated kinase polypeptides described herein may be chemically synthesized in whole or part using techniques that are well known in the art (see, e.g., Creighton, Proteins: Structures and Molecular Principles, W.H. Freeman & Co., NY, 1983).

Gene expression systems may be used for the synthesis of native and mutated polypeptides. Expression vectors containing the native or mutated polypeptide coding sequence and appropriate transcriptional/translational control signals, that are known to those skilled in the art may be constructed. These

Host-expression vector systems may be used to express kinase. These include, but are not limited to, microorganisms such as bacteria transformed with recombinant bacteriophage DNA, plasmid DNA or cosmid DNA expression vectors containing the coding sequence; yeast transformed with recombinant yeast expression vectors containing the coding sequence; insect cell systems infected with recombinant virus expression vectors (e.g., baculovirus) containing the coding sequence; plant cell systems infected with recombinant virus expression vectors (e.g., cauliflower mosaic virus, CaMV; tobacco mosaic virus, TMV) or transformed with recombinant plasmid expression vectors (e.g., Ti plasmid) containing the coding sequence; or animal cell systems. The protein may also be expressed in human gene therapy systems, including, for example, expressing the protein to augment the amount of the protein in an individual, or to express an engineered therapeutic protein. The expression elements of these systems vary in their strength and specificities.

Specifically designed vectors allow the shuttling of DNA between hosts such as bacteria-yeast or bacteria-animal cells. An appropriately constructed expression vector may contain: an origin of replication for autonomous replication in host cells, one or more selectable markers, a limited number of useful restriction enzyme sites, a potential for high copy number, and active promoters. A promoter is defined as a DNA sequence that directs RNA polymerase to bind to DNA and initiate RNA synthesis. A strong promoter is one that causes mRNAs to be initiated at high frequency.

The expression vector may also comprise various elements that affect transcription and translation, including, for example, constitutive and inducible promoters. These elements are often host and/or vector dependent. For example, when cloning in bacterial systems, inducible promoters such as the T7 promoter, pL of bacteriophage \(\lambda\), plac, ptrp, ptc (ptrp-lac hybrid promoter) and the like may be used; when cloning in insect cell systems, promoters such as the baculovirus polyhedrin promoter may be used; when cloning in plant cell systems, promoters derived from the genome of plant cells (e.g., heat shock promoters; the promoter for the small subunit of RUBISCO; the promoter for the chlorophyll a/b binding protein) or from plant viruses (e.g., the 35S RNA promoter of CaMV; the coat protein promoter of TMV) may be used; when cloning in mammalian cell systems, mammalian promoters (e.g., metallothionein promoter) or mammalian viral promoters, (e.g., adenovirus late promoter; vaccinia virus 7.5K promoter, SV40 promoter; bovine papilloma virus promoter; and Epstein-Barr virus promoter) may be used.

Various methods may be used to introduce the vector into host cells, for example, transformation, transfection, infection, protoplast fusion, and electroporation. The expression vector-containing cells are clonally propagated and individually analyzed to determine whether they produce the appropriate polypeptides.

Various selection methods, including, for example, antibiotic resistance, may be used to identify host cells that have been transformed. Identification of polypeptide expressing host cell clones may be done by several means, including but not limited to immunological reactivity with anti-kinase antibodies, and the presence of host cell-associated activity.

Expression of cDNA may also be performed using \textit{in vitro} produced synthetic mRNA. Synthetic mRNA can be efficiently translated in various cell-free systems, including but not limited to wheat germ
extracts and reticulocyte extracts, as well as efficiently translated in cell-based systems, including, but not limited, to microinjection into frog oocytes.

To determine the cDNA sequence(s) that yields optimal levels of activity and/or protein, modified cDNA molecules are constructed. A non-limiting example of a modified cDNA is where the codon usage in the cDNA has been optimized for the host cell in which the cDNA will be expressed. Host cells are transformed with the cDNA molecules and the levels of kinase RNA and/or protein are measured.

Levels of kinase protein in host cells are quantitated by a variety of methods such as immunoaffinity and/or ligand affinity techniques, kinase-specific affinity beads or specific antibodies are used to isolate 35S-methionine labeled or unlabeled protein. Labeled or unlabeled protein is analyzed by SDS-PAGE. Unlabeled protein is detected by Western blotting, ELISA or RIA employing specific antibodies.

Following expression of kinase in a recombinant host cell, polypeptides maybe recovered to provide the protein in active form. Several purification procedures are available and suitable for use. Recombinant kinase may be purified from cell lysates or from conditioned culture media, by various combinations of, or individual application of, fractionation, or chromatography steps that are known in the art.

In addition, recombinant kinase can be separated from other cellular proteins by use of an immunoaffinity column made with monoclonal or polyclonal antibodies specific for full length nascent protein or polypeptide fragments thereof. Other affinity based purification techniques known in the art may also be used.

Alternatively, the polypeptides may be recovered from a host cell in an unfolded, inactive form, e.g., from inclusion bodies of bacteria. Proteins recovered in this form may be solubilized using a denaturant, e.g., guanidinium hydrochloride, and then refolded into an active form using methods known to those skilled in the art, such as dialysis.

**Cell Growth Assays**

A variety of cell growth assays are known in the art and are useful in identifying fused ring heterocycle compounds (i.e. "test compounds") capable of inhibiting (e.g. reducing) cell growth and/or proliferation.

For example, a variety of cells are known to require specific kinases for growth and/or proliferation. The ability of such a cell to grow in the presence of a test compound may be assessed and compared to the growth in the absence of the test compound thereby identifying the anti-proliferative properties of the test compound. One common method of this type is to measure the degree of incorporation of label, such as tritiated thymidine, into the DNA of dividing cells. Alternatively, inhibition of cell proliferation may be assayed by determining the total metabolic activity of cells with a surrogate marker that correlates with cell number. Cells may be treated with a metabolic indicator in the presence and absence of the test compound. Viable cells metabolize the metabolic indicator thereby forming a detectable metabolic product. Where detectable metabolic product levels are decreased in the presence of the test compound relative to the absence of the test compound, inhibition of cell growth and/or proliferation is indicated. Exemplary metabolic indicators include, for example tetrazolium salts and AlamorBlue® (see Examples section below).

Example 1: Synthesis of the Compounds

Method 1

Step 1: Synthesis of S-bromo-2-fluoro-pyridine-3-carbaldehyde.

A solution of lithium di-iso-propylamine (5 mL, 35 mmol) in anhydrous THF (40 mL) was cooled to -78°C under nitrogen and n-butyl lithium (2.5 M in hexanes, 12 mL, 30 mmol) was added. The mixture was then stirred at -78 °C for 15 min before 5-bromo-2-fluoro-pyridine (5 g, 28 mmol) was added. The resulting mixture was then stirred at -78 °C for 90 min. N-formylpiperidine (4 mL, 36 mmol) was added very rapidly to the suspension at -78°C and the mixture stirred vigorously for 60 sec. The reaction was immediately quenched by the addition of a 10 % (w/v) aqueous solution of citric acid. The mixture was warmed to room temperature and distributed between water and dichloromethane. The aqueous phase was extracted three times with dichloromethane and the organic phases were combined, dried over sodium sulfate, filtered and concentrated. Crystallization of the crude product from cyclohexane afforded 5-bromo-2-fluoro-pyridine-3-carbaldehyde (2.993 g, 52% yield) as pale beige flaky crystals. 1H-NMR (500 MHz, d6-DMSO) δ 10.07 (s, 1H), 8.70 (dd, 1H), 8.55 (dd, 1H). MS: m/z 236, 238 [MNa+], 204, 206 [MH+], 176, 178 [MH-CO+].

Steps 2 and 3: Synthesis of 5-bromo-1H-pyrazolo[3,4-b]pyridine.

5-bromo-2-fluoro-pyridine-3-carbaldehyde (13.66 g, 66.96 mmol), pinacol (8.75 g, 74.0 mmol) and para-toluenesulfonic acid monohydrate (1.50 g, 7.89 mmol) were placed in a flask equipped with a DEAN-STARK-condenser and dissolved in anhydrous benzene (400 mL). The mixture was heated to reflux and solvent distilled off until the distillate remains clear and the remaining volume was approximately 200 mL. The mixture was diluted with ethyl acetate (300 mL) and washed with a saturated aqueous solution of sodium bicarbonate and brine, then dried over sodium sulfate, filtered and concentrated. The resulting residue was dissolved in a mixture of ethanol (400 mL) and di-iso-propyl-ethyl-amine (25 mL). Anhydrous hydrazine (15 ml, 0.48 mol)
was then added and the resulting mixture was stirred under reflux conditions for 4 h. The mixture was then concentrated to dryness and the resulting residue was distributed between water and toluene. The organic phase was washed with brine twice, dried over sodium sulfate, filtered and concentrated. The residue was dissolved in anhydrous ether (700 mL) and hydrogen chloride in anhydrous ether (2 M, 70 mL) was added slowly to the vigorously stirred solution. The precipitate was filtered off, washed with ether and hexane and then dried in vacuum. \(^{1}H\)-NMR (500 MHz, \(d_{6}\)-DMSO) \(\delta\) 10.31 (s, br, 1H), 8.86 (s, 1H), 8.37 (d, 1H), 7.88 (d, 1H), 6.08 (s, 1H), 3.56 (s, br), 1.27 (s, 6H), 1.19 (s, 6H). MS: \(m/z\) 198, 200 [MH\(^{+}\)].

The above solid was dissolved in a mixture of water (500 mL), ethanol (200 mL) and concentrated aqueous hydrochloric acid (50 mL) at 50-65°C. The mixture was then stirred at room temperature for 16 h before being neutralized to pH = 8 with sodium bicarbonate. The resulting precipitate was filtered off and the aqueous phase extracted three times with ethyl acetate. The combined organic phases are washed with brine, dried over sodium sulfate, filtered and concentrated. The resulting residue and the precipitate obtained are crystallized from ethanol to afford 5-bromo-1H-pyrazolo[3,4-b]pyridine (6.615 g, 50% yield) as a crystalline beige to pale olive-green solid. \(^{1}H\)-NMR (500 MHz, \(d_{6}\)-DMSO) \(\delta\) 13.91 (s, 1H), 8.60 (d, 1H), 8.54 (d, 1H), 8.16 (s, br, 1H). MS: \(m/z\) 198, 200 [MH\(^{+}\)].

**Step 4: Synthesis of 5-bromo-3-iodo-1H-pyrazolo[3,4-b]pyridine.**

5-bromo-1H-pyrazolo[3,4-b]pyridine (3.00 g, 15.2 mmol) and N-iodosuccinimide (3.60 g, 16.0 mmol) were dissolved in anhydrous dichloroethane (100 mL). The resulting mixture was stirred under reflux conditions for 6 h, cooled to room temperature and diluted with THF (300 mL). The resulting solution was washed with a saturated aqueous solution of sodium miosulfate (100 mL) and brine, then dried over magnesium sulfate, filtered and concentrated. The residue was triturated with a 1:1 mixture of dichloromethane and ether and then ether before being dried in vacuo to afford 5-bromo-3-iido-1H-pyrazolo[3,4-b]pyridine (3.795 g, 77% yield) as a beige-brown solid. \(^{1}H\)-NMR (500 MHz, \(d_{6}\)-DMSO) \(\delta\) 14.31 (s, 1H), 8.65 (d, 1H), 8.20 (d, 1H). **Step 5: Synthesis of 5-bromo-3-iido-1-(2-trimethylsilanyl-ethoxymethyl)-1H-pyrazolo[3,4-b]pyridine.**

Under nitrogen 5-bromo-3-iido-1H-pyrazolo[3,4-b]pyridine (2.68 g, 8.27 mmol) was dissolved in anhydrous DMF (40 mL). The solution was cooled to 0-5°C and an excess of dry sodium hydride added until further addition does not result in hydrogen formation. To the resulting suspension was added 2-trimethylsilanyl-ethoxymethylchloride (2.5 ml, 14 mmol) drop wise at 0-5°C. The resulting mixture was stirred at 0°C for 1 h and thereafter quenched by addition of methanol and subsequently of a saturated aqueous solution of ammonium chloride. The mixture was then concentrated to dryness at 50°C under reduced pressure. The resulting residue was distributed between water, brine and dichloromethane. The aqueous phase was then extracted with dichloromethane and the combined organic phases were dried over sodium sulfate, filtered and concentrated. The crude product was purified by flash silica gel chromatography using a gradient of ethyl acetate in hexanes to afford 5-bromo-3-iido-1-(2-trimethylsilanyl-ethoxymethyl)-1H-pyrazolo[3,4-b]pyridine (2.929 g, 78% yield) as a beige to brown solid. \(^{1}H\)-NMR (500 MHz, \(d_{6}\)-DMSO) \(\delta\) 8.85 (d, 1H), 8.40 (d, 1H), 5.85 (s, 2H), 3.69 (t, 2H), 0.92 (t, 2H), 0.11 (s, 9H).

**Step 1:** Synthesis of N,N-dimethyl-3-(5-(3-(morpholine-4-carbonyl)phenyl)-1-(2-(trimethylsilyl)ethoxy)methyl)-1H-pyrazolo[3,4-b]pyridin-3-yl)benzamide.

A mixture of (3-(3-iodo-1-((2-(trimethylsilyl)ethoxy)methyl)-1H-pyrazolo[3,4-b]pyridin-5-yl)phenyl)(morpholino)methanone (50 mg, 0.089 mmol), 3-(dimethylcarbamoyl)phenylboronic acid (34 mg.
0.177 mmol), [1,1'-Bis(diphenylphosphino)ferrocene]dichloropalladium(II) complex with dichloromethane (3.6 mg, 0.0045 mmol) and sodium carbonate (2M aqueous solution, 0.134 mL, 0.267 mmol) in acetonitrile (1 mL) was heated in a Personal microwave at 90 °C for 30 min. The resulting mixture was diluted with water and extracted with ethyl acetate. The organic layers were combined, dried over sodium sulfate, filtered and concentrated to dryness. Silica gel chromatography purification of the crude product afford N,N-dimethyl-3-(5-(3-(morpholine-4-carbonyl)phenyl)-1H-pyrazolo[3,4-b]pyridin-3-yl)benzamide as a clear oil. MS: m/z 586.2 [M+H⁺].

Step 2: Synthesis of N,N-dimethyl-3-(5-(3-(morpholine-4-carbonyl)phenyl)-1H-pyrazolo[3,4-b]pyridin-3-yl)benzamide.

A solution of N,N-dimethyl-3-(5-(3-(morpholine-4-carbonyl)phenyl)-1H-pyrazolo[3,4-b]pyridin-3-yl)benzamide in 5% of perchloric acid in acetic acid (1 mL) was stirred for 1 h at room temperature. Saturated sodium bicarbonate solution was then added to the solution slowly until pH ~ 8 and the mixture was stirred for 24 hours at room temperature. Ethyl acetate was then used for extraction and the organic layers were combined, dried over sodium sulfate, filtered and concentrated to dryness. Mass triggered reverse phase HPLC purification afforded N,N-dimethyl-3-(5-(3-(morpholine-4-carbonyl)phenyl)-1H-pyrazolo[3,4-b]pyridin-3-yl)benzamide (7.4 mg, 18% yield over two steps) as light yellow solids. 1H NMR (500 MHz, CD₃CAFCD₃) δ 2.99 (s, 3H), 3.10 (s, 3H), 3.46 (br, 2H), 3.61 (br, 2H), 3.76 (br, 4H), 7.40 (d, J = 7.0 Hz, 1H), 7.47 (d, J = 8.0 Hz, 1H), 7.52 (m, 2H), 7.64 (d, J = 7.5 Hz, 1H), 7.68 (s, 1H), 7.98 (m, 2H), 8.62 (s, 1H), 8.85 (br, 1H). MS: m/z 456.1 (M+H⁺).

Method 5

Step 1: Synthesis of methyl 3-(1H-pyrazolo[3,4-b]pyridin-5-yl)benzoate.
A mixture of 5-bromo-1H-pyrazolo[3,4-b]pyridine (2.00 g, 10.10 mmol), 3-(methoxycarbonyl)phenylboronic acid (2.20 g, 12.12 mmol), sodium bicarbonate (2.2 g, 6.00 mmol), and tetrakis(triphenylphosphine)palladium(0) (0.250 g, 0.202 mmol) in dioxane/water (40 mL/10 mL) was stirred at 110 °C for 15 hours. The mixture was then poured into ice water and extracted with ethyl acetate (3X). The organic layers were combined, dried over sodium sulfate, filtered and concentrated to dryness. Silica gel chromatography of the crude product afforded methyl 3-(1H-pyrazolo[3,4-b]pyridin-5-yl)benzoate (8) (1.65 g, 65% yield) as yellow solids. S: m/z 254.0 (M+H+).

Step 2: Synthesis of methyl 3-(3-iodo-1H-pyrazolo[3,4-b]pyridin-5-yl)benzoate
To a solution of methyl 3-(1H-pyrazolo[3,4-b]pyridin-5-yl)benzoate (1.65 g, 6.52 mmol) in dichloroethane (40 mL) was added NIS (1.81 g, 8.04 mmol) and the mixture was stirred at 70 °C for 6 hours. The solvent was removed by reduced pressure and the crude product was purified by silica gel chromatography to afford methyl 3-(3-iodo-1H-pyrazolo[3,4-b]pyridin-5-yl)benzoate (9) (988 mg, 40% yield). MS: m/z 379.9 (M+H+).

Step 3: Synthesis of 3-(3-iodo-1-((2-(trimethylsilyl)ethoxy)methyl)-1H-pyrazolo[3,4-b]pyridin-5-yl)benzoic acid.
To a solution of methyl 3-(3-iodo-1H-pyrazolo[3,4-b]pyridin-5-yl)benzoate (988 mg, 2.61 mmol) in DMF was added sodium hydride (60% in mineral oil, 525 mg, 13.03 mmol) at -40 °C. The mixture was stirred for 60 minutes before SEMCl (920 µL, 5.22 mmol) was added. The reaction was warmed to room temperature and quenched with methanol and water. Acetic acid was then used to adjust the pH to 4-5. The mixture was then extracted with ethyl acetate (3x) and the organic layers were combined, dried over sodium sulfate, filtered and concentrated to dryness. Silica gel chromatography purification of the resulting crude product afforded 3-(3-iodo-1-((2-(trimethylsilyl)ethoxy)methyl)-1H-pyrazolo[3,4-b]pyridin-5-yl)benzoic acid (200 mg, 15% yield) as solids. Water was then added to the mixture and extracted with ethyl acetate (3x). The organic layers were combined, dried over sodium sulfate, filtered and concentrated to dryness. Silica gel chromatography of the crude product afforded (4-(2-(dimethylamino)ethyl)piperazin-1-yl)3-(3-iodo-1-((2-(trimethylsilyl)ethoxy)methyl)-1H-pyrazolo[3,4-b]pyridin-5-yl)phenyl)methanone (110 mg, 43% yield) as off-white solids. * synthesized starting from 3-[3-(2-methoxy-phenyl)-1H-pyrazolo[3,4-b]pyridin-5-yl]-benzoic acid
dissolved in a mixture of 20 mL of acetonitrile and 10 mL of methanol. 131 mg (0.83 mmol) of 1-(2-

bis(diphenyolphosphino)ferrocenepalladium(II)-dichloride dichloromethane adduct(95.4 mg, 0.117 mmol),
acetonitrile (5 mL) and 2M aqueous Na₂CO₃ (5 mL). The vial was sealed, purged with N₂, and irradiated in a
Personal Chemistry Optimizer at 130°C for 30 min. The reaction mixture was diluted with EtOAc and acidified

combined organic phase was treated with brine, dried (Na₂SO₄), filtered and concentrated. The crude product
was dissolved in 10 mL of a solution consisting of 1 part HClO₄ (70%, ACS) and 20 parts glacial acetic acid,
and the solution was stirred at it for 4 h. The reaction mixture was concentrated under vacuum, and neutralized
to pH 7 with saturated NaHCO$_3$ followed by solid NaHCO$_3$. The aqueous phase was then acidified to pH 4 with acetic acid and extracted 5X with EtOAc. The combined organic extracts was treated with brine, dried (Na$_2$SO$_4$), filtered and concentrated. Trituration with Et$_2$O afforded the title compound as a greenish-brown powder (0.296 g, 81% yield). $^1$H-NMR (500 MHz, $d_6$-DMSO) $\delta$ 13.73 (br. s, 1H), 9.16 (s, 1H), 8.71(s, 1H), 8.40(s, 1H), 7.68(d, J=8.0 Hz, 1H), 7.48(t, J=8.0 Hz, 2H), 7.24(d, J=8.0 Hz, 1H), 7.10 (t, J=7.5 Hz 1H), 3.87(s, 3H); MS: m/z 353.1 [MH$^+$].

Method 46

STEP 1

STEP 2

STEP 3
Step 1: Synthesis of \(3-[3-(2-	ext{methoxy-phenyl})-1(2-	ext{trimethylsilanyl-ethoxymethyl})-1H-	ext{pyrazolo}[3,4-b]\text{pyridin-5-yl}]-	ext{phenyl})\text{-acetic acid.}\)

To a mixture of 3-(2-Methoxy-phenyl)-5-(4,4,5,5-te\text{tamethyl}-[1,3,2]dioxaborolan-2-yl)-1-(2- trimethylsilanyl-ethoxymethyl)-1H-pyrazolo[3,4-b]pyridine (500 mg, 1.04mmol) and 3-bromophenylacetic acid (268 mg, 1.25 mmol) in a 20 mL microwave reaction flask was added THF (3 mL), acetonitrile (3 mL) and sodium carbonate (3 mL, 1 N aqueous solution, 3 mmol). The mixture was bubbled with \(\text{N}_2\) for 1 min.

dicloro[1,1'-bis(diphenylphosphino)ferrocene]palladium(II) (73 mg, 10% mol) was added and the bubbling continued for another minute. The flask was sealed and irradiated with microwave in Emrys Optimizer at 120 °C for 20 min. The reaction mixture was partitioned between aqueous saturated sodium chloride and ethyl acetate (15 mL:15 mL). The aqueous layer was extracted with ethyl acetate (10 mL X 2). Normal work up of the combined organic layers and purification with flash chromatography on silica gel using a gradient of methanol in dichloromethane yielded 3-[3-(2-methoxy-phenyl)-1(2- trimethylsilanyl-ethoxymethyl)-1H-
pyrazolo[3,4-b]pyridin-5-yl]-phenyl\text{-N,N-dimethyl-acetamide} as a yellow solid (340 mg, 67% yield). MS: \(m/z\) 490 (M+H+).

Step 2: Synthesis of 2-[3-(2-Methoxy-phenyl)-1(2- trimethylsilanyl-ethoxymethyl)-1H-
pyrazolo[3,4-b]pyridin-5-yl]-phenyl\text{-N,N-dimethyl-acetamide.}\)

To a solution of 3-[3-(2-methoxy-phenyl)-1(2- trimethylsilanyl-ethoxymethyl)-1H-
pyrazolo[3,4-b]pyridin-5-yl]-phenyl\text{-acetid acid} (100 mg, 0.19 mmol), dimethylamine (2 N solution in THF, 0.19 mL, 0.38 mmol), diisopropylethylamine (49 mg, 0.38 mmol) in THF was added O-(7-azabenzotriazol-1-yl)-N,N,N',N'-tetramethyluroniumhexafluorophosphate (110 mg, 0.29 mmol). The resulting suspension was heated to 60 °C with stirring till the O-(7-azabenzotriazol-1-yl)-N,N,N',N'-tetramethyluroniumhexafluorophosphate completely dissolved. The THF was evaporated and the residue was used in the next step reaction without further purification. MS: \(m/z\) 517 (M+H+).

Step 3: Synthesis of 2-[3-(2-methoxy-phenyl)-1H-
pyrazolo[3,4-b]pyridin-5-yl]-phenyl\text{-N,N-dimethyl-acetamide.}\)

To the crude 2-[3-(2-methoxy-phenyl)-1(2- trimethylsilanylethoxymethyl)-1H-
pyrazolo[3,4-b]pyridin-5-yl]-phenyl\text{-N,N-dimethyl-acetamide} obtained in last step was added TFA (2 mL) and the resulting mixture was sonicated till the residue was completely dissolved. The TFA was evaporated. The residue was treated with ethylene diamine (0.2 mL) to scavenge the formaldehyde which generated from the de-protection of the trimethylsilanylethoxymethyl group. The resulting mixture was sonicated till the residue was completely dissolved to give a greenish blue solution. DMSO was added to make a 2 mL solution which was used in preperative LCMS purification on a reves phase column to yield 2-[3-(2-methoxy-phenyl)-1H-
pyrazolo[3,4-b]pyridin-5-yl]-phenyl\text{-N,N-dimethyl-acetamide} as a white solid (21 mg, 29% over two steps) MS: \(m/z\) 387 (M+H+). 1H NMR (500 MHz, DMSO-d6) δ 2.84 (s, 3H), 3.04 (s, 3H), 3.78 (s, 2H), 3.86 (s, 6H), 7.10 (t, 1H), 7.23 (d, 1H), 7.25 (d, 1H), 7.43 (t, 1H), 7.47 (t, 1H), 7.61 (s, 1H), 7.62 (d, 1H), 7.66 (d, 1H), 8.30 (s, 1H), 8.82 (d, sH), 13.82 (s, 1H).

Bioassays:

Kinase assays known to those of skill in the art may be used to assay the inhibitory activities of the compounds and compositions of the present invention. Kinase assays include, but are not limited to, the following examples.

Although the first of these examples uses the kinase domain of a mutant form of Abl T315I ("Abl T315I KD"), the kinase assays may use various forms of mutant and wild type enzymes, including, for example, the entire protein, the kinase domain, or a portion thereof (e.g. Abl Y393F). The kinases used in the assays may also be of varying phosphorylation states. In the c-Abl example, a mutant kinase at a zero phosphorylation state was used.

c-Abl Pyruvate Kinase/Lactate Dehydrogenase Coupled Enzyme Assay

In the c-Abl Pyruvate Kinase (PK)/Lactate Dehydrogenase (LDH) Coupled Assay the protein kinase dependant phosphorylation of a substrate peptide was coupled to the oxidation of NADH. The oxidation of NADH to NAD+ was detected by monitoring a decrease in absorbance at 340nm.

Materials: Abl substrate peptide = EAIYAAPFAKKK (SEQ ID NO: 1)-OH (Biopeptide, San Diego, CA); βNADH (Sigma Cat#N-8129, FW=709.4); 2M MgCl₂; 1M HEPES buffer, pH 7.5; Phosphoenolpyruvate (PEP) (Sigma Cat#P-7002, FW=234); Lactate dehydrogenase (LDH) (Worthington Biochemical Cat#2756); Pyruvate Kinase (PK) (Sigma Cat#P-9136); ATP (Sigma Cat#A-3377, FW=551); Greiner 384-well UV star plate; and purified and unphosphorylated T315I Abl kinase domain.

Stock Solutions: 10mM NADH (7.09 mg/ml in miliQH₂O) made fresh daily; 10 mM Abl substrate peptide (13.4mg/ml in miliQH₂O) stored at -20°C; 100 mM HEPES buffer, pH 7.5 (5 ml 1M stock + 45 ml miliQH₂O); 100mM MgCl₂ (5 ml 2M MgCl₂ + 95 ml dH₂O); 100mM PEP (23.4mg/ml in dH₂O) stored at -20°C; 10mM ATP (5.51mg/ml in dH₂O) stored at -20°C (diluted 50 µl into total of 10 ml miliQH₂O daily =50µM ATP working stock); 1000U/ml PK (U/mg varies with lot) flash-frozen under liquid N₂ and stored at -80°C; and 1000U/ml LDH (U/mg varies with lot) flash-frozen under liquid N₂ and stored at -80°C.
Standard Assay Setup for 384-well format (50µl reaction): 300µM NADH; 10mM MgCl₂; 2 mM PEP; 45U/ml PK; 60U/ml LDH; 200µM Abl substrate peptide; 2.5µl test compound (in DMSO); 2µg/ml Abl kinase domain; 10µM ATP; 100mM HEPES buffer. Positive controls contained DMSO with no test compound. Negative controls contained 5 µl of 0.5M EDTA (50mM in the assay). The dephosphorylated form of the c-Abl T315I mutant was used in the biochemical screening assays. The kinase reaction was initiated at time \( t=0 \) by the addition of ATP.

Activity was measured by following the time-dependent loss of NADH by absorbance spectroscopy at 340nm. The linear portion of the resulting progress curve was then analyzed by linear regression to get the activity in absorbance units/time, reported as the slope of that best fit line (moles/unit time can be calculated from using molar extinction coefficient for NADH at 340nm, 6250M⁻¹cm⁻¹).

Data was evaluated using the equation: \( Z=\frac{[3*(\sigma+\mu)]}{\mu} \) (Zhang, et al., 1999 J Biomol Screening 4(2) 67-73), where \( \mu \) denotes the mean and \( \sigma \) the standard deviation. The subscript designates positive or negative controls. The \( Z \) score for a robust screening assay should be \( \geq 0.50 \). The typical threshold \( =\mu-3^*\sigma \). Any value that falls below the threshold was designated a "hit".

Dose response was analyzed using the equation: \( y=\min+(\max-\min)/(1+10^{\text{compound-logic}o}) \), where \( y \) is the observed initial slope, \( \max=\text{the slope in the absence of inhibitor,} \) \( \min=\text{the slope at infinite inhibitor,} \) and the \( IC_{50} \) is the [compound] that corresponds to \( A \) the total observed amplitude (Amplitude=\( \max-\min \)).

To measure modulation, activation, or inhibition of Abl KD, a test compound was added to the assay at a range of concentrations. Inhibitors may inhibit Abl KD activity at an \( IC_{50} \) in the micromolar range, the nanomolar range, or, for example, in the subnanomolar range.

**Additional Kinase Assays**

In addition to the c-Abl PK/LDH coupled assay (above), homogeneous luminescence-based inhibitor screening assays were developed for c-Abl, MET, AurA, and PDK1 kinases (among others). Each of these assays made use of an ATP depletion assay (Kinase-Glo™, Promega Corporation, Madison, WI) to quantitate kinase activity. The Kinase-Glo™ format uses a thermostable luciferase to generate luminescent signal from ATP remaining in solution following the kinase reaction. The luminescent signal is inversely correlated with the amount of kinase activity.

Sigma Cat#85660-IMG), white Costar 384-well flat-bottom plate (VWR Cat#29444-088), PDK1 kinase (see below), Kinase-Glo™ (Promega Cat#V6712).

Stock Solutions: 1mM PDKtide substrate (1 mg in 200µl, as supplied by Upstate), stored at -20°C;

100mM HEPES buffer, pH 7.5 (5 ml 1M HEPES stock + 45 ml miliQH₂O); 10mM ATP (5.51mg/ml in dH₂O) stored at -20°C (diluted 25 µl into total of 10 ml H2O daily, 25µM ATP working stock); 100 mM MgCl₂; 10% Brij 35 stored at 2-8°C; 200µM Staurosporine, 2X Kinase-Glo™ reagent (made fresh or stored at -20°C).

Standard Assay Setup for 384-well format (20 µl kinase reaction, 40 µl detection reaction): 10mM MgCl₂; 0.01mM PDKtide; 1 µl test compound (in DMSO); 0.1 µg/ml PDK1 kinase; 5µM ATP; 10mM MgCl₂;

100mM HEPES + 0.01% Brij buffer. Positive controls contained DMSO with no test compound. Negative controls contained 10µM staurosporine. The kinase reactions were initiated at time t=0 by the addition of ATP. Kinase reactions were incubated at 21°C for 40 min, then 20 µl of Kinase-Glo™ reagent were added to each well to quench the kinase reaction and initiate the luminescence reaction. After a 20 min incubation at 21°C, the luminescence was detected in a plate-reading luminometer.

Preparation of Co-expression Plasmid

A lambda phosophatase co-expression plasmid was constructed as follows.

An open-reading frame for Aurora kinase was amplified from a Homo sapiens (human) HepG2 cDNA library (ATCC HB-8065) by the polymerase chain reaction (PCR) using the following primers:

Forward primer: TCAAAAAAGAGGCAGTGGGCTTTG (SEQ ID NO:4)

Reverse primer: CTGAATTTGCTGTGATCCAGG (SEQ ID NO:5).

The PCR product (795 base pairs expected) was gel purified as follows. The PCR product was purified by electrophoresis on a 1% agarose gel in TAE buffer and the appropriate size band was excised from the gel and eluted using a standard gel extraction kit. The eluted DNA was ligated for 5 minutes at room temperature with topoisomerase into pSB2-TOPO. The vector pSB2-TOPO is a topoisomerase-activated, modified version of pET26b (Novagen, Madison, WI) wherein the following sequence has been inserted into the Ndel site: CATAATGGGCCATCATACTCATCAGCGGTGTCATATGTCCTTCT (SEQ ID NO:6) and the following sequence inserted into the BamHI site: AAGGGGGATCTAAACTGCA GAGATCC (SEQ ID NO:7). The sequence of the resulting plasmid, from the Shine-Dalgarno sequence through the "original" Ndel site, the stop site and the "original" BamHI site is as follows:

AAGGGGGATCTATACTCATATGGGCCATCATACTCATCAGCGGTGTCATATGTCCTTCT (SEQ ID NO:8) [ORF] AAGGGGGATCTAAACTGCA GAGATCC (SEQ ID NO:9). The Aurora kinase expressed using this vector has 14 amino acids added to the N-terminus (MetGlyHisHisHisHIsHisGlyGlyHisMetSerLeu) (SEQ ID NO:10) and four amino acids added to the C-terminus (GluGlyGlySer) (SEQ ID NO:11).
The phosphatase co-expression plasmid was then created by inserting the phosphatase gene from lambda bacteriophage into the above plasmid (Matsui T, et al., Biochem. Biophys. Res. Commun., 2001, 284:798-807). The phosphatase gene was amplified using PCR from template lambda bacteriophage DNA (HindIII digest, New England Biolabs) using the following oligonucleotide primers:

Forward primer (PPfor): GCAGAGATCCGAATTCCAGCTC
CGTCGACGGATGGAGTGAAAGAGATGC (SEQ ID NO. 12)

Reverse primer (PPrev): GGTGGTGGCTGAGTGCGGCCA
GCTTTCATCATCGGCCTTTCTCCCTGTAC (SEQ ID NO. 13).

The PCR product (744 base pairs expected) was gel purified. The purified DNA and non-co-expression plasmid DNA were then digested with Sau3A and XhoI restriction enzymes. Both the digested plasmid and PCR product were then gel purified and ligated together for 8 h at 16°C with T4 DNA ligase and transformed into Top10 cells using standard procedures. The presence of the phosphatase gene in the co-expression plasmid was confirmed by sequencing. For standard molecular biology protocols followed here, see also, for example, the techniques described in Sambrook et al., Molecular Cloning: A Laboratory Manual, Cold Spring Harbor Laboratory, NY, 2001, and Ausubel et al., Current Protocols in Molecular Biology, Greene Publishing Associates and Wiley Interscience, NY, 1989.

This co-expression plasmid contains both the Aurora kinase and lambda phosphatase genes under control of the lac promoter, each with its own ribosome binding site. By cloning the phosphatase into the middle of the multiple cloning site, downstream of the target gene, convenient restriction sites are available for subcloning the phosphatase into other plasmids. These sites include Sau3A, SalI and EcoRI between the kinase and phosphatase and HindIII, NotI and XhoI downstream of the phosphatase.

**Protein Kinase Expression**

An open-reading frame for c-Abl was amplified from a *Mus musculus* (mouse) cDNA library prepared from freshly harvested mouse liver using a commercially available kit (Invitrogen) by PCR using the following primers:

Forward primer: GACAAGTGGAATGGGAC (SEQ ID NO: 14)
Reverse primer: CGCCCTGTTTCCCAGGCTC (SEQ ID NO: 15).

The PCR product (846 base pairs expected) was purified from the PCR reaction mixture using a PCR cleanup kit (Qiagen). The purified DNA was ligated for 5 minutes at room temperature with topoisomerase into pSGX3-TOPO. The vector pSGX3-TOPO is a topoisomerase-activated, modified version of pET26b (Novagen, Madison, Wisconsin) wherein the following sequence has been inserted into the NdeI site: CATATGTCCCTT (SEQ ID NO: 16) and the following sequence inserted into the BamHI site: AAGGGGATCCATCACATTCCCATGCTGAC (SEQ ID NO: 17). The sequence of the resulting plasmid, from the Shine-Dalgamo sequence through the stop site and the BamHI, site is as follows: AAGGAGGA

GATATACATAGTC CACC (SEQ ID NO: 18) [ORF]AAGGGGATCCATCACATTCCCATGCTGAC (SEQ ID NO: 19). The c-Abl expressed using this vector had three amino acids added to its N-terminus (Met Ser Leu) and 8 amino acids added to its C-terminus (GluGlyHisHisHisHisHis) (SEQ ID NO: 20).

A c-Abl/phosphatase coexpression plasmid was then created by subcloning the phosphatase from the Aurora co-expression plasmid of Example 1 into the above plasmid. Both the Aurora co-expression plasmid and the Abl non-co-expression plasmid were digested 3 hrs with restriction enzymes EcoRI and NotI. The DNA
fragments were gel purified and the phosphatase gene from the Aurora plasmid was ligated with the digested c-Abl plasmid for 8 h at 16°C and transformed into Top10 cells. The presence of the phosphatase gene in the resulting construct was confirmed by restriction digestion analysis.

This plasmid codes for c-Abl and lambda phosphatase co-expression. It has the additional advantage of two unique restriction sites, XbaI and NdeI, upstream of the target gene that can be used for subcloning of other target proteins into this phosphatase co-expressing plasmid.

The plasmid for Abl T315I was prepared by modifying the Abl plasmid using the Quick Change mutagenesis kit (Stratagene) with the manufacturer's suggested procedure and the following oligonucleotides:

Mm05582dS4 5'-CCACCATTCT ACAATACTTTG AGTTCATGACCTATGGG-3' (SEQ ID NO:21)
Mm05582dA4 5'-CCCATAGGTCACTGACTCATGTATGTTAATGTTTGG-3' (SEQ ID NO:22).

Protein from the phosphatase co-expression plasmids was purified as follows. The non-co-expression plasmid was transformed into chemically competent BL21(DE3)Codon+RIL (Stratagene) cells and the co-expression plasmid was transformed into BL21(DE3) pSA0145 (a strain that expresses the lytic genes of lambda phage and lyses upon freezing and thawing (Crabtree S, Cronan JE Jr. J Bacteriol 1984 Apr;158(l):354-6)) and plated onto petri dishes containing LB agar with kanamycin. Isolated single colonies were grown to mid-log phase and stored at -80°C in LB containing 15% glycerol. This glycerol stock was streaked on LB agar plates with kanamycin and a single colony was used to inoculate 10 ml cultures of LB with kanamycin and chloramphenicol, which was incubated at 30°C overnight with shaking. This culture was used to inoculate a 2 L flask containing 500 ml of LB with kanamycin and chloramphenicol, which was grown to mid-log phase at 37°C and induced by the addition of IPTG to 0.5 mM final concentration. After induction flasks were incubated at 21°C for 18 h with shaking.

The c-Abl T315I KD (kinase domain) was purified as follows. Cells were collected by centrifugation, lysed in diluted cracking buffer (50 mM Tris HCl, pH 7.5, 500 mM KCl, 0.1% Tween 20, 20 mM Imidazole, with sonication, and centrifuged to remove cell debris. The soluble fraction was purified over an IMAC column charged with nickel (Pharmacia, Uppsala, Sweden), and eluted under native conditions with a gradient of 20 mM to 500 mM imidazole in 50 mM Tris, pH 7.8, 500 mM NaCl, 10 mM methionine, 10% glycerol.

The protein was then further purified by gel filtration using a Superdex 75 preparative grade column equilibrated in GF5 buffer (10 mM HEPES, pH 7.5, 100 mM methionine, 500 mM NaCl, 5 mM DTT, and 10% glycerol). Fractions containing the purified c-Abl T315I KD kinase domain were pooled. The protein obtained was 98% pure as judged by electrophoresis on SDS polyacrylamide gels. Mass spectroscopic analysis of the purified protein showed that it was predominantly singly phosphorylated. The protein was then dephosphorylated with Shrimp Alkaline Phosphatase (MBI Fermentas, Burlington, Canada) under the following conditions: 100 U Shrimp Alkaline Phosphatase/mg of c-Abl T315I KD, 100 mM MgCl₂, and 250 mM additional NaCl. The reaction was run overnight at 23°C. The protein was determined to be unphosphorylated by Mass spectroscopic analysis. Any precipitate was spun out and the soluble fraction was separated from reactants by gel filtration using a Superdex 75 preparative grade column equilibrated in GF4 buffer (10 mM HEPES, pH 7.5, 100 mM methionine, 150 mM NaCl, 5 mM DTT, and 10% glycerol).

**Purification of Met:**

The cell pellets produced from half of a 12 L SfP insect cell culture expressing the kinase domain of human Met were resuspended in a buffer containing 50 mM Tris-Cl pH 7.7 and 250 mM NaCl, in a volume of...
approximately 40 ml per 1 L of original culture. One tablet of Roche Complete, EDTA-free protease inhibitor cocktail (Cat# 1873580) was added per 1 L of original culture. The suspension was stirred for 1 hour at 4°C. Debris was removed by centrifugation for 30 minutes at 39,800 x g at 4°C. The supernatant was decanted into a 500 ml beaker and 10 ml of 50% slurry of Qiagen Ni-NTA Agarose (Cat# 30250) that had been pre-equilibrated in 50 mM Tris-HCl pH 7.8, 500 mM NaCl, 10% Glycerol, 10 mM Imidazole, and 10 mM Methionine, were added and stirred for 30 minutes at 4°C. The sample was then poured into a drip column at 4°C and washed with 10 column volumes of 50 mM Tris-HCl pH 7.8, 500 mM NaCl, 10% Glycerol, 10 mM Imidazole, and 10 mM Methionine. The protein was eluted using a step gradient with two column volumes each of the same buffer containing 50 mM, 200 mM, and 500 mM Imidazole, sequentially. The 6x Histidine tag was cleaved overnight using 40 units of TEV protease (Invitrogen Cat# 10127017) per 1 mg of protein while dialyzing in 50 mM Tris-HCl pH 7.8, 500 mM NaCl, 10% Glycerol, 10 mM Imidazole, and 10 mM Methionine at 4°C. The 6x Histidine tag was removed by passing the sample over a Pharmacia 5 ml IMAC column (Cat# 17-0409-01) charged with nickel and equilibrated in 50 mM Tris-HCl pH 7.8, 500 mM NaCl, 10% Glycerol, 10 mM Imidazole, and 10 mM Methionine. The cleaved protein bound to the Nickel column at a low affinity and was eluted with a step gradient. The step gradient was run with 15% and then 80% of the B-side (A-side = 50 mM Tris-HCl pH 7.8, 500 mM NaCl, 10% Glycerol, 10 mM Imidazole, and 10 mM Methionine; B-side = 50 mM Tris-HCl pH 7.8, 500 mM NaCl, 10% Glycerol, 500 mM Imidazole, and 10 mM Methionine) for 4 column volumes each. The Met protein eluted in the first step (15%), whereas the non-cleaved Met and the cleaved Histidine tag eluted in the 80% fractions. The 15% fractions were pooled after SDS-PAGE gel analysis confirmed the presence of cleaved Met; further purification was done by gel filtration chromatography on an Amersham Biosciences HiLoad 16/60 Superdex 200 prep grade (Cat# 17-1069-01) equilibrated in 50 mM Tris-HCl pH 8.5, 150 mM NaCl, 10% Glycerol and 5 mM DTT. The clearest fractions were combined and concentrated to ~10.4 mg/ml by centrifugation in an Amicon Ultra-15 10,000 Da MWCO centrifugal filter unit (Cat# UFC901024).

Purification of Aurora 2:

The Sf9 insect cell pellets (~ 18 g) produced from 6 L of cultured cells expressing human Aurora-2 were resuspended in 50 mM Na Phosphate pH 8.0, 500 mM NaCl, 10% glycerol, 0.2% n-octyl-β-D-glucopyranoside (BOG) and 3 mM β-Mercaptoethanol (BME). One tablet of Roche Complete, EDTA-free protease inhibitor cocktail (Cat# 1873580) and 85 units Benzonase (Novagen Cat#70746-3) were added per 1 L of original culture. Pellets were resuspended in approximately 50 ml per 1 L of original culture and were then sonicated on ice with two 30-45 sec bursts (100% duty cycle). Debris was removed by centrifugation and the supernatant was passed through a 0.8 μm syringe filter before being loaded onto a 5 ml Ni²⁺ HiTrap column (Pharmacia). The column was washed with 6 column volumes of 50 mM Na Phosphate pH 8.0, 500 mM NaCl, 10% glycerol, 3 mM BME. The protein was eluted using a linear gradient of the same buffer containing 500 mM Imidazole. The eluant (24 ml) was cleaved overnight at 4°C in a buffer containing 50 mM Na Phosphate pH 8.0, 500 mM NaCl, 10% glycerol, 3 mM BME and 10,000 units of TEV (Invitrogen Cat# 10127-017). The protein was passed over a second nickel affinity column as described above; the flow-through was collected. The cleaved protein fractions were combined and concentrated using spin concentrators. Further purification was done by gel filtration chromatography on a S75 sizing column in 50 mM Na Phosphate (pH 8.0), 250 mM NaCl, 1 mM EDTA, 0.1 mM AMP-PNP or ATP buffer, and 5 mM DTT. The clearest fractions were combined and
concentrated to approximately 8-1 lmg/ml, and were either flash frozen in liquid nitrogen in 120 µl aliquots and stored at -80°C, or stored at 4°C.

**Purification of PDK1:**

Cell pellets produced from 6 L of Sf9 insect cells expressing human PDK1 were resuspended in a buffer containing 50mM Tris-HCl pH 7.7 and 250mM NaCl in a volume of approximately 40 mL per 1 L of original culture. One tablet of Roche Complete, EDTA-free protease inhibitor cocktail (Cat# 1873580) and 85 units Benzonase (Novagen Cat#70746-3)) were added per 1 L of original culture. The suspension was stirred for 1 hour at 4°C. Debris was removed by centrifugation for 30 minutes at 39,800 x g at 4°C. The supernatant was decanted into a 500 mL beaker and 10 mL of a 50% slurry of Qiagen Ni-NTA Agarose (Cat# 30250) that had been pre-equilibrated in 50mM Tris-HCl pH 7.8, 500mM NaCl, 10% Glycerol, 10mM Imidazole, and 10mM Methionine, were added and stirred for 30 minutes at 4°C. The sample was then poured into a drip column at 4°C and washed with 10 column volumes of 50mM Tris-HCl pH 7.8, 500mM NaCl, 10% Glycerol, 10mM Imidazole, and 10mM Methionine. The protein was eluted using a step gradient with two column volumes each of the same buffer containing 50mM, and 500mM Imidazole, sequentially. The 6x Histidine tag was cleaved overnight using 40 units of TEV protease (Invitrogen Cat# 10127017) per lmg of protein while dialyzing in 50mM Tris-HCl pH 7.8, 500mM NaCl, 10% Glycerol, 10mM Imidazole, and 10mM Methionine at 4°C. The 6x Histidine tag was removed by passing the sample over a Pharmacia 5 ml IMAC column (Cat# 17-0409-01) charged with Nickel and equilibrated in 50mM Tris-HCl pH 7.8, 500mM NaCl, 10% Glycerol, 10mM Imidazole, and 10mM Methionine. The cleaved protein eluted in the flow-through, whereas the uncleaved protein and the His-tag remained bound to the Ni-column. The cleaved protein fractions were combined and concentrated using spin concentrators. Further purification was done by gel filtration chromatography on an Amersham Biosciences HiLoad 16/60 Superdex 200 prep grade (Cat# 17-1069-01) equilibrated in 25mM Tris-HCl pH 7.5, 150mM NaCl, and 5mM DTT. The cleanest fractions were combined and concentrated to ~15mg/ml by centrifugation in an Amicon Ultra-15 10,000 Da MWCO centrifugal filter unit (Cat# UFC901024).

**Cell Assays:**

MV4-11 and THP cells were maintained in Iscove's Modified Dulbecco's Medium supplemented with 10% fetal bovine serum (FBS) and penicillin/streptomycin. Ba/F3 cells were maintained in RPMI 1640 supplemented with 10% FBS, penicillin/streptomycin and 5ng/ml recombinant mouse IL-3.

**Cell Survival Assays**

Compounds were tested in the following assays in duplicate.

96-well XTT assay: Cells were grown in growth media containing various concentrations of compounds (duplicates) on a 96-well plate for 72 hours at 37°C. The starting cell number was 5000-8000 cells per well and volume was 120 µl. At the end of the 72-hour incubation, 40 µl of XTT labeling mixture (50:1 solution of sodium 3'-[1-(phenylamino-carbonyl)-3,4-tetrazolium]-bis (4-methoxy-6-nitro) benzene sulfonic acid hydrate and Electron-coupling reagent: PMS (N-methyl dibenzopyrazine methyl sulfate) were added to each well of the plate. After an additional 2-6 hours of incubation at 37°C, the absorbance reading at 405nm with background correction at 650nm was measured with a spectrophotometer.

384-well AlamarBlue assay: 90 µl of cell suspension were plated onto each well of a 384-well plate preprinted with 0.5 µl of compound in DMSO or DMSO only. The starting cell number was 4000 cells per
well. After a 72-hour incubation, 10 µl of AlamarBlue solution (440 µM resazurin in PBS) were then added to each well of the plate. After an additional 2-hour incubation at 37°C, fluorescence was measured using a TECAN plate reading fluorometer with excitation at 535nm and emission at 591nm.

Cells (Ba/F3 cells transfected with WT BCR-ABL, other kinases, or T3151, Y253F, or other mutant forms of BCR-ABL) were grown in the absence of IL-3 at least 1 week before the assay. The day before assay, the cells were fed with fresh media so that at the time of assay the cells were in log phase. Ba/F3 cells that had been grown in the absence of IL-3 for at least 1 week were resuspended in RPMI 1640 so that each well of a 96-well plate would contain approximately 200,000 cells. Cells were distributed in a 96-well plate containing serially diluted concentrations of test compounds. Cells were typically incubated with or without test compounds for 60-120 minutes at 5% CO2, 37°C. The incubation was performed with or without other additives such as 10% FCS or 50% human plasma. After incubation of compounds, lysis buffer was added and incubated for 10-15 minutes; the lysate was cleared by centrifugation.

To make the ELISA plate, commercially available Anti-ABL antibodies (e.g. Ab-3, Calbiochem OP20) were prepared at a concentration of 0.125 μg/ml in coating buffer (0.1M Na-carbonate, pH 9.5), and plated at 10 μl per plate (12.5 μl 100 μg/ml Ab/10ml). In a high binding multi-well plate, 100 μl Ab in coating buffer were added to each well, and each plate was covered with a plate seal and incubated overnight at 4°C. Excess antibody was removed and the ELISA plate was washed 3-4 times with 200 μl of wash buffer (0.05% Tween in PBS, pH 7.4). 150 μl of lysate (see above) were transferred to the ELISA plate. Plates were sealed and incubated 2 hours at room temperature. The detection antibody (e.g. HRP conjugated anti-pTyr or unconjugated o>p-Y 4G10, Upstate) was prepared in assay diluent. The antibody was diluted 1:1000 (stocks=2 μg/μl, 200 μg in 100μl; f.c.=2 μg/ml) in assay diluent and 10 ml of diluted antibody per plate were added. The lysate was removed from the ELISA plates, and wells were washed four times with 200 μl of wash buffer per well. 100 μl of detection antibody was added to each well; the plate was covered, and incubated 1 hr at room temperature (21°C). Excess detection antibody was removed from the ELISA plates, and the wells were washed four times with 200 μl of wash buffer per well.

If necessary, (i.e. for unconjugated anti-pTyr antibody) secondary antibody (goat anti-rabbit HRP) was diluted 1:3000 in assay diluent (3.33 µl per 10 ml diluent) and added at 10 ml of diluted antibody per plate. Excess secondary antibody was removed from the ELISA plate, and the plate was washed four times with 200 µl per well of wash buffer.

Substrate Reagent A and Substrate Reagent B (Pierce Cat#37070 SuperSignal ELISA Pico Chemiluminescent Substrate) were added immediately before use (10 ml resultant solution per plate). 100 µl substrate were added per well, mixed for 1 minute, and chemiluminescent signal was measured with a luminometer.
