SUBSTITUTED BICYCLE HETEROCYCLIC DERIVATIVES USEFUL AS ROMK CHANNEL INHIBITORS

CROSS REFERENCE TO RELATED APPLICATIONS

This application claims the benefit of Indian Provisional Application Serial No. 20161 1037609, filed November 3, 2016, which is incorporated herein in its entirety.

DESCRIPTION

The present invention generally relates to substituted benzylamine compounds useful as inhibitors of ROMK channel activity. Provided herein are substituted benzylamine compounds, compositions comprising such compounds, and methods of their use. The invention further pertains to pharmaceutical compositions containing at least one compound according to the invention that are useful for the treatment of conditions related to ROMK channel activity, including cardiovascular diseases.

The renal outer medullary potassium (ROMK, Kir 1.1) channel is a weak inward rectifying K+ channel with a key role in renal K+ recycling and secretion (Ho et al, Nature, 1993, 362, 31-38; Shuck et al., The Journal of Biological Chemistry, 1994, 269(39), 24261-24270; Lee and Hebert, American Journal of Physiology-Renal Physiology, 1995, 268(6), F1124-F1131; Lu et al, The Journal of Biological Chemistry, 2002, 277, 37881-37887; and Hebert et al., Physiological Reviews, 2005, 85:319-371). In the thick ascending limb (TAL) of a nephron, ROMK channel activity provides the K+ gradient necessary for Na and Cl reabsorption by the Na+-K^+ - 2Cl^- (NKCC2) co-transporter. In the distal convoluted tubule (DCT) and cortical collecting duct (CCD), ROMK channels form the major secretory pathway for K+ and as a result, play an important role in K^+ homeostasis under physiological conditions (Welling and Ho, American Journal of Physiology-Renal Physiology, 2009, 297(4): F849-F863).

Multiple lines of evidence indicate that inhibition of ROMK channel activity results in natruresis, diuresis and reduced blood pressure. Therefore, ROMK inhibition may offer a novel mechanism of blood pressure regulation and diuresis in patients suffering from hypertension, congestive heart failure or any other edematous disease conditions. The activity of NKCC2 transporter is tightly coupled with ROMK activity in the TAL region and homozygous loss of function mutations in ROMK in humans result in a disease phenotype (renal salt wasting, increased aldosterone levels, metabolic alkalosis,
reduction in blood pressure) very similar to that of NKCC2 homozygous mutations but with a milder hypokalemia (Simon et al., *Nature Genetics*, 1996, 14: 152-1.56). In addition, humans identified with heterozygous ROMK mutations from the Framingham Heart Study presented with reduced blood pressure (Ji et al, *Nature Genetics*, 2008, 40(5): 592-599). Similar to human genetics, mouse genetics also support the role of ROMK in Na+ reabsorption in the kidney and overall blood pressure regulation (Lu et al., *The Journal of Biological Chemistry*, 2002, 277, 37881-37887; and Lorenz et al., *The Journal of Biological Chemistry*, 2002, 277: 37871-37880). Furthermore, pharmacological blockade of the ROMK channel has been shown to induce natriuresis and diuresis in rats upon acute dosing and in dogs upon both acute and prolonged dosing (Tang et al., *Bioorganic and Medicinal Chemistry Letter*, 2013, 23: 5829-5832; Garcia et al. *The Journal of Pharmacology and Experimental Therapeutics*, 2014, 348: 153-164; Walsh et al., *ACS Medicinal Chemistry Letters*, 2015, 6: 747-752; and Dajee et al., *Circulation*, 2014, 130: A12397). Since the ROMK channel is also implicated in regulation of net K+ secretion in the distal part of the nephron, it is believed that ROMK inhibition in this region will mitigate the K+ wasting and hypokalemia associated with loop and thiazide diuretics. Acute or prolonged (up to 122 days) ROMK antagonism does not lead to kaliuresis or hypokalemia in dogs (Garcia et al., *The Journal of Pharmacology and Experimental Therapeutics*, 2014, 348: 153-164; Walsh et al., *ACS Medicinal Chemistry Letters*, 2015, 6: 747-752; Dajee et al., *Circulation*, 2014, 130: A12397). Together, these data suggest that inhibition of ROMK may produce diuretic efficacy that is equivalent to or better than currently available loop diuretics and with potentially lower incidence of hypokalemia.

In view of the numerous conditions that are contemplated to benefit by treatment involving inhibition of ROMK, it is immediately apparent that new compounds capable of inhibiting ROMK and methods of using these compounds should provide substantial therapeutic benefits to a wide variety of patients.

The present invention relates to a new class of substituted bicyclic heterocyclic compounds found to be effective inhibitors of ROMK.

Each ring of such a group containing a heteroatom can contain one or two oxygen or sulfur atoms and/or from one to four nitrogen atoms provided that the total number of heteroatoms in each ring is four or less, and further provided that the ring contains at least one carbon atom. The nitrogen and sulfur atoms may optionally be oxidized and the nitrogen atoms may optionally be quaternized. a heteroatom can contain one or two oxygen or sulfur atoms and/or from one to four 
nitrogen atoms provided that the total number of heteroatoms in each ring is four or less 
and each ring has at least one carbon atom. The fused rings completing the bicyclic 
group are aromatic and may contain other heteroatoms or only carbon atoms. The 
nitrogen and sulfur atoms may optionally be oxidized and the nitrogen atoms may 
optionally be quaternized. Bicyclic and tricyclic heteroaryl groups must include only

The phrase "pharmaceutically acceptable" is employed herein to refer to those 
compounds, materials, compositions, and/or dosage forms which are, within the scope of 
sound medical judgment, suitable for use in contact with the tissues of human beings and 
animals without excessive toxicity, irritation, allergic response, or other problem or 
complication, commensurate with a reasonable benefit/risk ratio.

The compounds of Formula (I) can be provided as amorphous solids or crystalline 
solids. Lyophilization can be employed to provide the compounds of Formula (I) as 
amorphous solids.

It should further be understood that solvates (e.g., hydrates) of the compounds of 
Formula (I) are also within the scope of the present invention. The term "solvate" means 
a physical association of a compound of Formula (I) with one or more solvent molecules, 
whether organic or inorganic. This physical association includes hydrogen bonding. In
certain instances the solvate will be capable of isolation, for example when one or more solvent molecules are incorporated in the crystal lattice of the crystalline solid. "Solvate" encompasses both solution-phase and isolable solvates. Exemplar solvates include hydrates, ethanolates, methanolates, isopropanolates, acetomtrile solvates, and ethyl acetate solvates. Methods of solvation are known in the art.

Various forms of prodrugs are well known in the art and are described in:

a) *The Practice of Medicinal Chemistry*, Camille G. Wermuth et al., Ch 31, (Academic Press, 1996);

b) *Design of Prodrugs*, edited by H. Bundgaard, (Elsevier, 1985);

In addition, compounds of Formula (I), subsequent to their preparation, can be isolated and purified to obtain a composition containing an amount by weight equal to or greater than 99% of a compound of Formula (I) ("substantially pure"), which is then used or formulated as described herein. Such "substantially pure" compounds of Formula (I) are also contemplated herein as part of the present invention.

Compounds of the formula I and/or the Examples herein may in some cases form salts which are also within the scope of this invention. Reference to a compound of the formula I and/or Examples herein is understood to include reference to salts thereof, unless otherwise indicated. The term "salt(s)", as employed herein, denotes acidic and/or basic salts formed with inorganic and/or organic acids and bases. Zwitterions (internal or inner salts) are included within the term "salt(s)" as used herein (and may be formed, for example, where the R substituents comprise an acid moiety such as a carboxyl group). Also included herein are quaternary ammonium salts such as alkylammonium salts. Pharmacologically acceptable (i.e., non-toxic, physiologically acceptable) salts are preferred, although other salts are useful, for example, in isolation or purification steps which may be employed during preparation. Salts of the compounds of the formula I may be formed, for example, by reacting a compound I with an amount of acid or base, such as an equivalent amount, in a medium such as one in which the salt precipitates or in an aqueous medium followed by lyophilization. As used herein, "pharmacologically
acceptable salts" refer to derivatives of the disclosed compounds wherein the parent compound is modified by making acid or base salts thereof. Examples of pharmaceutically acceptable salts include, but are not limited to, mineral or organic acid salts of basic groups such as amines; and alkali or organic salts of acidic groups such as carboxylic acids. The pharmaceutically acceptable salts include the conventional non-toxic salts or the quaternary ammonium salts of the parent compound formed, for example, from non-toxic inorganic or organic acids. Compounds in accordance with Formula (I) can be administered by any means suitable for the condition to be treated, which can depend on the need for site-specific treatment or quantity of Formula (I) compound to be delivered.

Also embraced within this invention is a class of pharmaceutical compositions comprising a compound of Formula (I) and one or more non-toxic, pharmaceutically-acceptable carriers and/or diluents and/or adjuvants (collectively referred to herein as "earner" materials) and, if desired, other active ingredients. The compounds of Formula (I) may be administered by any suitable route, preferably in the form of a pharmaceutical composition adapted to such a route, and in a dose effective for the treatment intended. The compounds and compositions of the present invention may, for example, be administered orally, mucosally, or parentally including intravascular!, intravenously, intraperitoneal!, subcutaneously, intramuscularly, and intrasternally in dosage unit formulations containing conventional pharmaceutically acceptable carriers, adjuvants, and vehicles. For example, the pharmaceutical carrier may contain a mixture of mannitol or lactose and microcrystalline cellulose. The mixture may contain additional components such as a lubricating agent, e.g. magnesium stearate and a disintegrating agent such as crospovidone. The carrier mixture may be filled into a gelatin capsule or compressed as a tablet. The pharmaceutical composition may be administered as an oral dosage form or an infusion, for example.

For oral administration, the pharmaceutical composition may be in the form of, for example, a tablet, capsule, liquid capsule, suspension, or liquid. The pharmaceutical composition is preferably made in the form of a dosage unit containing a particular amount of the active ingredient. For example, the pharmaceutical composition may be provided as a tablet or capsule comprising an amount of active ingredient in the range of from about 0.1 to 1000 mg, preferably from about 0.25 to 250 mg, and more preferably from about 0.5 to 100 mg. A suitable daily dose for a human or other mammal may vary widely depending on the condition of the patient and other factors, but, can be determined using routine methods.

Any pharmaceutical composition contemplated herein can, for example, be
delivered orally via any acceptable and suitable oral preparations. Exemplary oral preparations, include, but are not limited to, for example, tablets, troches, lozenges, aqueous and oily suspensions, dispersible powders or granules, emulsions, hard and soft capsules, liquid capsules, syrups, and elixirs. An aqueous suspension can be prepared, for example, by admixing at least one
compound of Formula (I) with at least one excipient suitable for the manufacture of an aqueous suspension. Exemplary excipients suitable for the manufacture of an aqueous suspension, include, but are not limited to, for example, suspending agents, such as, for example, sodium carboxymethylcellulose, methylcellulose, hydroxypropylmethyl-cellulose, sodium alginate, alginic acid, polyvinyl-pyrrolidone, gum tragacanth, and gum acacia; dispersing or wetting agents, such as, for example, a naturally-occurring phosphatide, e.g., lecithin; condensation products of alkyne oxide with fatty acids, such as, for example, polyoxyethylene stearate; condensation products of ethylene oxide with long chain aliphatic alcohols, such as, for example heptadecaethylene-oxyctanol; condensation products of ethylene oxide with partial esters derived from fatty acids and hexitols, such as, for example, polyoxyethylene sorbitol monooleate; and condensation products of ethylene oxide with partial esters derived from fatty acids and hexitol anhydrides, such as, for example, polyethylene sorbitan monooleate. An oily suspension can also contain at least one thickening agent, such as, for example, beeswax; hard paraffin; and cetyl alcohol. In order to provide a palatable oily suspension, at least one of the sweetening agents already described hereinabove, and/or at least one flavoring agent can be added to the oily suspension. An oily suspension can further contain at least one preservative, including, but not limited to, for example, an anti-Oxidant, such as, for example, butylated hydroxyanisol, and alpha-tocopherol.

Dispersible powders and granules can, for example, be prepared by admixing at least one compound of Formula (I) with at least one dispersing and/or wetting agent; at least one suspending agent; and/or at least one preservative. Suitable dispersing agents, wetting agents, and suspending agents are as already described above. Exemplary preservatives include, but are not limited to, for example, anti-oxidants, e.g., ascorbic acid. In addition, dispersible powders and granules can also contain at least one
excipient, including, but not limited to, for example, sweetening agents; flavoring agents; and coloring agents.

An emulsion of at least one compound of Formula (I) thereof can, for example, be prepared as an oil-in-water emulsion. The oily phase of the emulsions comprising compounds of Formula (I) may be constituted from known ingredients in a known manner. The oil phase can be provided by, but is not limited to, for example, a vegetable oil, such as, for example, olive oil and arachis oil; a mineral oil, such as, for example, liquid paraffin; and mixtures thereof. While the phase may comprise merely an emulsifier, it may comprise a mixture of at least one emulsifier with a fat or an oil or with both a fat and an oil. Suitable emulsifying agents include, but are not limited to, for example, naturally-occurring phosphatides, e.g., soy bean lecithin; esters or partial esters derived from fatty acids and hexitol anhydrides, such as, for example, sorbitan monooleate; and condensation products of partial esters with ethylene oxide, such as, for example, polyoxyethylene sorbitan monooleate. Preferably, a hydrophilic emulsifier is included together with a lipophilic emulsifier which acts as a stabilizer. It is also preferred to include both an oil and a fat. Together, the emulsifier(s) with or without stabilizer(s) make-up the so-called emulsifying wax, and the wax together with the oil and fat make up the so-called emulsifying ointment base which forms the oily dispersed phase of the cream formulations. An emulsion can also contain a sweetening agent, a flavoring agent, a preservative, and/or an antioxidant. Emulsifiers and emulsion stabilizers suitable for use in the formulation of the present invention include Tween 60, Span 80, cetostearyl alcohol, myristyl alcohol, glyceryl monostearate, sodium lauryl sulfate, glyceryl distearate alone or with a wax, or other materials well known in the art.

The compounds of Formula (I) can, for example, also be delivered intravenously, subcutaneously, and/or intramuscularly via any pharmaceutically acceptable and suitable injectable form. Exemplary injectable forms include, but are not limited to, for example, sterile aqueous solutions comprising acceptable vehicles and solvents, such as, for example, water, Ringer's solution, and isotonic sodium chloride solution; sterile oil-in-water microemulsions; and aqueous or oleaginous suspensions.

Formulations for parenteral administration may be in the form of aqueous or non-aqueous isotonic sterile injection solutions or suspensions. These solutions and suspensions may be prepared from sterile powders or granules using one or more of the

The compounds may be dissolved in water, polyethylene glycol, propylene glycol, ethanol, corn oil, cottonseed oil, peanut oil, sesame oil, benzyl alcohol, sodium chloride, tragacanth gum, and/or various buffers. Other adjuvants and modes of administration are well and widely known in the pharmaceutical art. The active ingredient may also be administered by injection as a composition with suitable carriers including saline, dextrose, or water, or with cyclodextrin (i.e. Captisol), cosolvent solubilization (i.e. propylene glycol) or micellar solubilization (i.e. Tween 80).

The sterile injectable preparation may also be a sterile injectable solution or suspension in a non-toxic parenterally acceptable diluent or solvent, for example, as a solution in 1,3-butanediol. Among the acceptable vehicles and solvents that may be employed are water, Ringer's solution, and isotonic sodium chloride solution. In addition, sterile, fixed oils are conventionally employed as a solvent or suspending medium. For this purpose any bland fixed oil may be employed, including synthetic mono- or diglycerides. In addition, fatty acids such as oleic acid find use in the preparation of injectables.

A sterile injectable oil-in-water microemulsion can, for example, be prepared by 1) dissolving at least one compound of Formula (I) in an oily phase, such as, for example, a mixture of soybean oil and lecithin; 2) combining the Formula (I) containing oil phase with a water and glycerol mixture; and 3) processing the combination to form a microemulsion.

METHODS OF PREPARATION

The compounds of the present invention may be synthesized by many methods available to those skilled in the art of organic chemistry. A compendium of synthetic methods which may be applicable to the preparation of compounds of the present invention may be found in Larock, R.C., Comprehensive Organic Transformations, VCH, New York (1989). General synthetic schemes for preparing compounds of the present invention are described below. These schemes are illustrative and are not meant to limit the possible techniques one skilled in the art may use to prepare the compounds disclosed herein. Different methods to prepare the compounds of the present invention will be evident to those skilled in the art. In the description of the synthetic methods described below, it is to be understood that all proposed reaction conditions, including choice of solvent, reaction atmosphere, reaction temperature, duration of the experiment and workup procedures, are typically chosen to be the conditions standard for that reaction, which should be readily recognized by one skilled in the art. Restrictions to the substituents that are compatible with the reaction conditions will be readily apparent to one skilled in the art and alternate methods must then be used. It will also be recognized that another major consideration in the planning of any synthetic route in this field is the judicious choice of the protecting group used for protection of the reactive functional groups present in the compounds. An authoritative account describing the many alternatives is Greene et al. (Protective Groups in Organic Synthesis, Wiley and Sons (1991)). Additionally, the various steps in the synthesis may be performed in an alternate sequence in order to give the desired compound or compounds. Examples of compounds of the present invention prepared by methods described in the general schemes are given in the preparations and examples section set out hereinafter. Preparation of homochiral examples may be earned out by techniques known to one skilled in the art. For example, homochiral compounds may be prepared by separation of racemic products by chiral phase preparative HPLC. Alternatively, the example compounds may be prepared by methods known to give enantiomerically enriched products.

The reactions and techniques described in this section are performed in solvents appropriate to the reagents and materials employed and are suitable for the transformations being effected. Also, in the description of the synthetic methods described below, it is to be understood that all proposed reaction conditions, including
choice of solvent, reaction atmosphere, reaction temperature, duration of the experiment and work up procedures, are chosen to be the conditions standard for that reaction, which should be readily recognized by one skilled in the art. It is understood by one skilled in the art of organic synthesis that the functionality present on various portions of the molecule must be compatible with the reagents and reactions proposed. Such restrictions to the substituents that are compatible with the reaction conditions will be readily apparent to one skilled in the art and alternate methods must then be used. This will sometimes require a judgment to modify the order of the synthetic steps or to select one particular process scheme over another in order to obtain a desired compound of the invention. It will also be recognized that another major consideration in the planning of any synthetic route in this field is the judicious choice of the protecting group used for protection of the reactive functional groups present in the compounds described in this invention. An authoritative account describing the many alternatives to the trained practitioner is Greene et al. [Protective Groups in Organic Synthesis, Third Edition, Wiley and Sons (1999)).

NMR Employed in Characterization of Examples:

$^1$H NMR spectra were obtained with Bruker or JEOL fourier transform spectrometers operating at frequencies as follows: $^1$HNMR: 400 MHz or 300 MHz (Broker). $^{13}$C NMR: 100 MHz or 75 MHz (Bruker). Spectra data are reported in the format: chemical shift (multiplicity, coupling constants, and number of hydrogens).

Chemical shifts are specified in ppm downfield of a tetramethylsilane internal standard (δ units, tetramethylsilane = 0 ppm) and/or referenced to solvent peaks, which in $^1$H NMR spectra appear at 2.49 ppm for CD2HSOCD3, 3.30 ppm for CD2HOD, and 7.24 ppm for CHCl, and which in $^{13}$C NMR spectra appear at 39.7 ppm for CD3SOCD3, 49.0 ppm for CD3OD, and 77.0 ppm for CDCl. All $^{13}$C NMR spectra were proton decoupled.

BIOLOGICAL ASSAYS

The pharmacological properties of the compounds of this invention may be confirmed by a number of biological assays. The exemplified biological assays, which follow, have been carried out with compounds of the invention.

Thallium Flux Assay

Solutions and reagents: Thallium flux assay was performed using FluxOR kit (F10017, Life Technologies). Loading buffer, assay buffer and stimulus buffer were prepared using kit components. HBSS (Hank's balanced salt solution, Cat# 14025-092) was purchased separately from Life Technologies.

To prepare 10 ml of loading buffer: 10 μ of FluxOR dye (reconstituted in DMSO) was first added to 100 μ of powerload concentrate and this mix along with 100 μ of Probenicid (100X) was then added to 9.79 ml of HBSS. Assay buffer (10 ml) was prepared by addition of 2 ml of FluxOR chloride free buffer (5X), 100 μl of Probenicid (100X), and 0.2 ml of Ouabain (13.77 mM) to 7.7 ml of deionized water. Stimulus buffer was composed of 15 mM Tl2SO4, 0.75 mM K2SO4 in FluxOR chloride free buffer (diluted to 1X using deionized water). The final concentration of Tl2SO4 and K2SO4 in the assay plate was 3 mM and 0.15 mM, respectively.

Plating and induction of cells: The CHO T-Rex hROMK (human Kir1.1) stable cell line was maintained in Ham's F12 media supplemented with 10% FBS, 1% Penicillin-Streptomycin, 500 μg/ml Zeocin and 10 μg/ml Biasticidin at 37 °C in a 5% CO2 incubator. One day before the experiment, the cells were dissociated by incubation with Versene solution (15040-066, Life Technologies) for 10 minutes at 37 °C followed by addition of growth media. The cell suspension was centrifuged at 1200 rpm for 5 min. After discarding the supernatant, the cells were resuspended in fresh growth media and cell concentration was determined using a hemocytometer. Next, 0.5 μg/ml of Doxycycline was added to the cell suspension to induce hROMK channel expression and 50 μl (10,000 cells/well) of cell suspension was added to each well of a poly-D lysine coated 384 well black, optically clear bottom plate (6007718, Perkin Elmer). The assay plate was kept at 37 °C in a 5% CO2 incubator.

Assay protocol: On the day of experiment, media was removed and loading buffer
was added (30 µl/ well) to the assay plate. The cells were incubated in the loading buffer for 30 minutes at 37 °C. The loading buffer was then replaced by assay buffer (30 µl/ well) followed by addition of test compounds or controls. The cells were incubated with compounds for 30 minutes and the plate was then mounted on FlexStation (Molecular Devices) for fluorescence read out with excitation and emission wavelengths at 488 and 525 nm, respectively. Each well was read for 90 sec at 2 sec interval and the stimulus buffer was added after 20 seconds of baseline recording. The final DMSO concentration was either 0.5 or 1% in the assay plate. Positive and negative controls were defined by addition of DMSO or 3 µM of a standard ROMK inhibitor, respectively, to the wells instead of a test compound.

Data analysis: The slope (over a period of 15 seconds) of fluorescence increase after stimulus buffer addition was exported from SoftMax Pro into a custom made software where it was converted to % inhibition. A 10-point concentration response curve was used to estimate the IC50 value of test compounds.

The data in Table 3 is reported with two significant figures.

ROMK Manual Patch Clamp Assay

Cell culture conditions: Cells were maintained in conditions similar to those for Thallium flux assay. hROMK channel expression was induced by adding 0.6 μg/ml of Doxycycline 16-24 hrs prior to the experiments. On the day of experiment, the cells were dissociated using Versene, resuspended in growth media and plated onto coverslips 15 minutes prior to use.

Electrophysiology: The coverslip plated with cells was placed in the experiment chamber perfused with bath solution composed of (in mM): 135 NaCl, 5 KCl, 2 CaCl₂, 1 MgCl₂, 10 HEPES, 5 Glucose (pH 7.4). Patch pipettes with resistance between 2-5 Megaohms, when filled with a solution containing (in mM): 135 KCl, 1 EGTA, 1 MgCl₂, 10 HEPES, 2 Na₂ATP (pH 7.3), were used to form gigaseals. The cells were voltage clamped at -75 mV in whole-cell configuration using an Axopatch 200b or Multiclamp 700b (Molecular Devices) amplifier controlled by pClamp Software (Molecular Devices). The current was recorded by applying a voltage step to -120 mV every 10 seconds. For each compound, 4-6 concentrations were applied for 3-8 minutes in a successive manner starting with the lowest concentration. At the end of the experiment, the cells were perfused with bath solution containing 2mM Ba²⁺ to isolate the contribution of hROMK current.

Data analysis: Raw current values (5 traces each for control, different compound concentration and Ba²⁺ treatment groups) were exported from Clampfit into Microsoft Excel where the current remaining after application of Ba²⁺ was subtracted from raw current to obtain hROMK specific current. These hROMK current values (average of 5 traces for each group) were then imported into a custom made template to generate a concentration response curve, which was subsequently fitted with a four parameter equation to calculate the IC₅₀ value of the test compound.

The data in Table 4 is reported with two significant figures.
hERG Manual Patch Clamp Assay

hERG electrophysiology assay: The experimental compounds were assessed for hERG activity on HEK 293 cells stably expressing hERG channels using patch clamp technique. Coversiips plated with hERG expressing cells were placed in the

experimental chamber and were perfused with a solution composed of (in mM): 140 NaCl, 4 KCl, 1.8 CaCl₂, 1 MgCl₂, 10 Glucose, 10 HEPES (pH 7.4, NaOH) at room temperature. Borosilicate patch pipettes had tip resistances of 2-4 Mohms when filled with an internal solution containing: 130 KCl, 1 MgCl₂, 1 CaCl₂, 10 EGTA, 10 HEPES, 5 ATP-K₂ (pH 7.2, KOH). The cells were clamped at -80 mV in whole cell configuration using an Axopatch 200B (Axon instruments, Union City, CA) patch clamp amplifier controlled by pClamp (Axon instruments) software. Upon formation of a gigaseal, the following voltage protocol was repeatedly (0.05 Hz) applied to record tail currents: depolarization step from -80 mV to +20 mV for 2 seconds followed by a hyperpolarization step to -65 mV (3 seconds) to elicit tail currents. Compounds were applied after stabilization of tail current. First, tail currents were recorded in presence of extracellular solution alone (control) and subsequently, in extracellular solution containing increasing compound concentrations. Each compound concentration was applied for 2-5 minutes. The percentage inhibition at each concentration was calculated as reduction in peak tail current with respect to the peak tail current recorded in the presence of control solution. Data analysis was performed in a custom made template. The percent inhibitions at different concentrations were plotted to obtain a concentration response curve, which was subsequently fitted with a four parameter equation to calculate hERG IC₅₀ value. A lower hERG % Inhibition value indicates less inhibition of the hERG current.
