DESCRIPTION

FIELD OF THE INVENTION

[0001] The present application claims priority from provisional application Serial No. 60/477,939, filed June 13, 2003, and is divided from EP Application 04 736 545.7.

[0002] The present invention is directed to formulations comprising microspheres of estradiol and cholesterol, and microspheres of progesterone, having contraceptive and hormone-replacement effects. The formulations are compounded for prolonged or delayed release and facilitate administration at intervals of about four weeks or more.

BACKGROUND OF THE INVENTION

[0003] The ovarian/menstrual cycle is a complex event characterized by an estrogen-rich follicular phase and, after ovulation, a progesterone-rich luteal phase. Each phase lasts about 14 days resulting in an inter-menstrual interval of about 28 days. The endometrial tissue responds to the changes in hormonal levels.

[0004] The onset of menstruation is the beginning of a new menstrual cycle and is counted as day one. During a span of about five to seven days, the superficial layers of the endometrium, which grew and developed during the antecedent ovarian/menstrual cycle, are sloughed because demise of the corpus luteum in the non-fertile menstrual cycle is associated with the loss of progesterone secretion. Ovarian follicular maturation occurs progressively resulting in a rise in the circulating levels of estrogen, which in turn leads to new endometrial proliferation.

[0005] The dominant ovarian follicle undergoes ovulation at mid-cycle, generally between menstrual cycle days 12 to 16 and is converted from a predominantly estrogen source to a predominantly progesterone source (the corpus luteum). The increasing level of progesterone in the blood converts the proliferative endometrium to a secretory phase in which the tissue proliferation has promptly abated, leading to the formation of endometrial glands or organs. When the ovulated oocyte is viable and fertilized, its progressive embryonic cleavage, the secretory endometrium and the conceptus can interact to bring about implantation, beginning about six to eight days after fertilization.

[0006] If an ongoing pregnancy is to be established by implantation, the embryo will attach and burrow into the secretory endometrium and begin to produce human chorionic gonadotropin (HCG). The HCG in turn stimulates extended corpus luteum function, i.e., the progesterone function remains elevated, and menses does not occur in the fertile menstrual cycle. Pregnancy is then established.

[0007] In the non-fertile menstrual cycle, the waning level of progesterone in the blood causes the endometrial tissue to be sloughed. This starts a subsequent menstrual cycle.

[0008] Because endometrial proliferation serves to prepare the uterus for an impending pregnancy, manipulation of hormones for the uterine environment can provide contraception. For example, estrogens are known to decrease follicle stimulating hormone secretion by feedback inhibition. Under certain circumstances, estrogens can also inhibit luteinizing hormone secretion, once again by negative feedback. Under normal circumstances the spike of circulating estrogen found prior to ovulation induces the surge of gonadotrophic hormones that occurs just prior to and resulting in ovulation. High doses of estrogen can prevent conception probably due to interference with implantation.

[0009] Progestins can also provide contraception. Endogenous progesterone is responsible for the gestational changes in the endometrium and the cyclic changes of cells and tissue in the cervix and the vagina. Administration of progestin makes the cervical mucus thick, tenacious and cellular, which is believed to impede spermatozoal transport. Administration of progestin also inhibits luteinizing hormone secretion and blocks ovulation in humans.

[0010] There are a number of contraceptive formulations currently on the market that can be classified readily into several general types. The first of these are known as monophasic formulations. Monophasic formulations contain a constant amount of estrogen and progestin. Nuisance side effects with monophasic formulation pills depend on the balance between the estrogen and progestin component of the pill. For example, with a relatively dominant progestin pill, the formulation will, over time, result in a depletion of both estrogen and progestin receptors. The result, which might be expected, is an under stimulated or atrophic
endometrium, which may eventually cause either un-pill amenorrhea or breakthrough bleeding or spotting due to poor epithelialization. On the other hand, with a relatively dominant estrogenic preparation, it is possible that prolonged use could result in endometrial growth with the development of unsupported fragile stroma and subsequent spotting or breakthrough bleeding.

[0012] A significant problem with this type of formulation is the low dose of steroids at the beginning of the package, which makes these pills vulnerable to drug interactions, or missed pills, which may lead to breakthrough ovulation. The beginning of the package is the critical time in terms of breakthrough ovulation since the user has just completed a seven day drug-free interval during which follicular development may begin. Even if pregnancy does not occur, breakthrough ovulation can lead to poor cycle control.

[0013] 17-β-estradiol (E₂) is the most potent natural estrogen found in human beings and is the major secretory product of the ovary. It is readily oxidized in the body to estrone, E₁ which in turn can be hydrated to estriol. These transformations take place mainly in the liver, where there is free interconversion between E₁ and estradiol. All three of these natural estrogens are excreted in the urine as glucuronides and sulfates, along with a host of related, minor products in watersoluble complexes. It is widely known that, following oral administration of micronized E₂, the incremental circulation of estrogen is principally the less active species E₁, which reaches a peak concentration many times greater than that of E₂. The conversion of E₂ to E₁ and subsequently to other metabolites takes place during absorption from the intestine and passage through the liver. This extensive metabolism greatly limits the oral effectiveness of the natural estrogens and their esters. Indeed, because of their limited oral efficacy, E₂ and its esters are generally administered by intramuscular injections.

[0014] Progesterone (P₄) is the active natural progestin, which occurs in the corpus luteum, placenta and adrenal cortex. Like E₂, P₄ is also ineffective by oral administration because of its rapid metabolism in the intestinal epithelium and in the liver, and is therefore only administered intramuscularly.

[0015] Because of their limited oral effectiveness, workers in the art consider these natural female sex hormones as undesirable in the formulation of oral contraceptives. Instead, workers have focused on the fabrication and administration of synthetic estrogens and progestins for contraceptive purposes. The use of synthetic derivatives has also replaced natural substances in the treatment of menopause, threatened abortion, etc. However, these synthetic derivatives are more likely to cause toxic side effects than are the relatively safe endogenous hormones.

[0016] While chemical modifications of natural hormones exhibit enhanced oral activity, they also can cause a variety of undesirable side effects. For example, synthetic derivatives of natural hormones are known to have an adverse stimulating effect on the protein synthesis of the liver (possibly promoting thrombosis) and exhibit a diabetogenic effect, in contrast to natural sex hormones.

[0017] Synthetic estrogen, for example, is rapidly resorbed in the stomach and intestinal track. Because it is easily metabolized, it is rapidly absorbed in the mucus membrane of the small intestine and/or undergoes rapid chemical changes. Consequently, large individual differences in bio-availability can result. Further, synthetic estradiols can lead to an undesirable accumulation of certain xenobiotics and are known to exhibit carcinogenic properties.

[0018] Synthetic progestins are also known to exhibit undesirable side effects including, for example, masculinization and adverse effects on cholesterol levels, triglyceride levels and high-density lipoprotein levels. Synthetic progestins can also cause fluid retention and depression.

[0019] An additional undesirable side effect that can affect subjects undergoing synthetic hormonal contraceptive treatment is the reduction/cessation of natural hormone production. Many subjects also experience an undesirable hormone imbalance resulting from the cessation of ovulation due to the contraceptive effect of administered synthetic hormones.
Pharmaceutical formulations that include endogenous hormones are disclosed in US 6 287 693. That specification discloses particles consisting of a mixture of estradiol and cholesterol, and particles comprising progesterone.

**SUMMARY OF THE INVENTION**

[0021] According to one aspect of the invention, there is provided a formulation having contraceptive and hormone replacement effects in a female mammal comprising microspheres of 17-β-estradiol and cholesterol, and microspheres of progesterone, wherein the 17-β-estradiol is 45 to 66% amorphous and 35 to 55 % crystalline, and wherein the formulation has an estradiol dissolution rate (EDR) of 20% or less.

[0022] The invention further provides a formulation of the invention for use in contraception in a female mammal.

[0023] The invention further provides a formulation of the invention for use in hormone replacement therapy in a female mammal in the first five years of menopause.

[0024] The present invention allows administration of the natural hormones with a prolonged life in the organism by means of a depot system. The administration of the natural hormones precipitates the negative feedback effect while providing replacement of the inhibited endogenous hormones.

[0025] Thus, the present invention allows simultaneous contraceptive and hormone-replacement effects to be obtained with a formulation comprising a contraceptive-effective and hormone-replacement effective amount of a combination of natural hormones or hormone-mimetics. The formulation comprises at least one estrogen and at least one progestin. Preferably, the formulation comprises the naturally occurring hormones 17-β-estradiol (E2) and progesterone (P4).

[0026] By administering effective amounts of E2 and P4, the formulations of the present invention provide effective and reliable contraception without the undesirable side effects commonly associated with contraceptives formulated with orally active synthetic hormones. Additionally, because the formulations are compounded to produce a prolonged dissolution profile, the hormones have high mean residence times and avoid the shortcomings of the traditional short half-life of the natural hormones. Among other things, the formulations of the present invention are prepared in accordance with methods disclosed in US Patent No 5360616 and crystallized according to methods disclosed in US Patent No. 6528094 B1.

[0027] The formulations of the present invention provide effective hormone-replacement benefits. Because the formulations are compounded with naturally occurring hormones, administration of those formulations serves to restore or supplement the naturally occurring hormones otherwise produced in a female mammal of reproductive age. Conventional contraceptives comprised of orally-active, synthetic hormones do not provide such hormone-replacement benefits.

[0028] The estrogen and progestin agents of the formulations of the instant invention are present in the formulation in a contraceptive-effective and hormone-replacement-effective amount. On a unit dose basis, formulations of the present invention may comprise about 5 to about 15 mg of 17-β-estradiol and/or about 200 to about 500 mg of progesterone. Particularly preferred embodiments are formulations that comprise about 9 mg of 17-β-estradiol and about 400 mg of progesterone per unit dose. Thus, the term "contraceptive-effective and hormone-replacement effective amount" of 17-β-estradiol and progesterone, when referring to a mammal, particularly a female human, is meant to refer to a formulation comprising 17-β-estradiol and progesterone in a weight ratio of about 1:40. Preferably, the weight ratio is about 9:400. The term "unit dose" refers to an amount sufficient to effect both contraception and hormone-replacement therapy in one subject throughout at least one complete menstrual cycle.

[0029] In one embodiment, the formulation comprises a plurality of microspheres that comprise at least one of 17-β-estradiol and progesterone, and the microspheres are suspended in an aqueous vehicle for administration. (As used herein, the term microspheres includes microparticles, microcapsules, liposomes, and the like.) Preferably, the estradiol and progesterone in the microsphere are in crystalline form.

[0030] In accordance with a further aspect of the invention, the formulation comprises an aqueous preparation comprising microspheres of an estrogen and/or a progestin. The microspheres are preferably about 25 μm to about 105 μm in diameter; more preferably about 35 μm to about 75 μm. The microspheres are preferably compounded with other agents, carriers, and excipients such that the formulation is suitable for parenteral administration by hypodermic syringe.
[0031] A simultaneous contraceptive and hormone-replacement effect can be achieved by administering to a subject a formulation comprising a contraceptive-effective and hormone-replacement-effective amount of 17-β-estradiol and progesterone. The subject of such administration is preferably a female mammal of reproductive years, also referred to herein as a "fertile female."

[0032] The invention further provides a formulation comprising particles of 17-β-estradiol and cholesterol, and particles of progesterone, and wherein the 17-β-estradiol and progesterone are in a weight ratio of 3:40 to 1:100 and wherein the 17-β-estradiol is 45 to 65% amorphous and 35 to 55% crystalline, and wherein the formulation has an estradiol dissolution rate (EDR) of 20% or less, for use in contraception in a female mammal.

[0033] Also disclosed herein is a method for simultaneous contraception and hormone-replacement effects which comprises administering to a subject a formulation comprising microspheres of at least one of 17-β-estradiol and progesterone. Preferably, the formulation is a dispersion or suspension of said microspheres in a liquid vehicle. The 17-β-estradiol and progesterone are present in the formulation in a contraceptive-effective and hormone-replacement-effective amount. In the case of female humans, the effective amount of 17-β-estradiol is about 9 mg and the effective amount of progesterone is about 400 mg.

[0034] A preferred method for achieving simultaneous contraception and hormone-replacement effect includes parenteral administration of an estrogen/progesterin formulation into a subject. Preferably, the formulation is administered by intramuscular injection. The formulations of the present invention are delayed or prolonged release formulations that can be effectively administered at intervals of about four weeks without loss of the contraceptive or hormone-replacement effect during the intervening period.

[0035] The formulations of the present invention can be compounded into a variety of forms for storage, shipment, or administration. The formulations can be compounded as dispersions of the microspheres in an aqueous vehicle for parenteral administration, the particle size being preferably about 25 µm to about 105 µm, and more preferably about 35 µm to about 75 µm.

[0036] A kit may comprise a formulation comprising a contraceptive and a hormone-replacement effective amount of 17-β-estradiol and progesterone, wherein the formulation preferably comprises about 9 mg of 17-β-estradiol and about 400 mg of progesterone.

[0037] The present invention, through the use of contraceptive-effective and hormone-replacement effective amounts of 17-β-estradiol and progesterone, realizes an important advantage in that it can substantially minimize or eliminate the undesirable side effects commonly associated with conventional, synthetic hormone-containing contraceptive formulations. Additionally, through the use of effective amounts of these endogenous hormones, the present invention realizes another important advantage in that it can provide subjects with natural hormones at levels equivalent to the average natural monthly production, thereby avoiding undesirable hormone imbalances.

**DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS**

[0039] The present invention allows contraceptive-effective and hormone replacement-effective amounts of 17-β-estradiol and progesterone to be administered to a subject in a controlled manner to substantially minimize and/or eliminate undesirable side effects commonly associated with synthetic hormone contraceptive therapies. Additionally, the present invention provides these natural hormones at levels equivalent to their average natural monthly production.

[0040] The term "17-β-estradiol," as used herein, encompasses any pharmaceutically-acceptable, estrogrenically-active form of 17-β-estradiol, i.e., estra-1,3,5(10)-triene-3,17-β-diol itself, which has the formula:
or one of its esters. 17-β-estradiol can be obtained from natural sources or made synthetically. Suitable esters of 17-β-estradiol, for purposes of the present invention, include, for example, 3-monoesters such as estradiol benzoate and estradiol 3-acetate; 17-monoesters such as estradiol cypionate, estradiol 17-propionate, estradiol 17-acetate, estradiol 17-heptanoate (estradiol enanthate), estradiol 17-undecanoate (estradiol undecylate) and estradiol 17-valerate; and 3,17-diesters such as estradiol dipropionate and estradiol diacetate, and the like, and combinations thereof.

[0041] The term "progesterone," as used herein, refers to pregn-4-ene-3,20-dione, i.e., the compound of the formula:

\[
\text{CH}_3
\]

and is intended to include progesterone derived from natural sources as well as that made synthetically.

[0042] In preferred embodiments of the present invention, the formulations comprise aqueous suspensions of microspheres comprising an estrogen (17-β-estradiol (E2)) and a progestin (progesterone (P4)) in a contraceptive-effective and hormone-replacement-effective amount.

[0043] Additionally, the microspheres of such embodiments comprise the additional endogenous steroid cholesterol.

[0044] The additional endogenous steroid is preferably inert relative to the estrogen/progestin agents and has substantially reduced solubility in biological fluids such as blood. When so formulated, the cholesterol/estradiol/progesterone microspheres are compounded in such a way that the estrogen/progestin agents are uniformly distributed throughout the relatively inert steroid such that the dissolution of those agents is retarded but nonetheless continuous and substantially steady. Preferably, the inert steroid, as well as the estrogen and progestin, are in crystalline form within the microsphere. As discussed more fully below, the substantially steady rate of dissolution of the active agents thus facilitates a controlled release of the active agents over an extended period. Preferably, the extended period is at least one complete menstrual cycle, and in the case of a female human it is at least about 4 weeks.

[0045] In embodiments of the invention, the contraceptive-effective and hormone replacement-effective amounts of E2 and P4 are amounts that are suitable for providing a simultaneous contraceptive and hormone-replacement effect. In particular, with respect to the contraceptive effect, the effective amount of E2 and P4 is an amount that is sufficient to act on the hypothalamus and the pituitary of the subject being treated to inhibit the liberation of gonadotrophic hormones necessary for maintaining normal ovarian function.

[0046] In addition, the hormone-replacement-effective amount of E2 and P4 is an amount sufficient to substantially replace the natural supply of these hormones whose endogenous production is reduced and/or eliminated with the cessation of ovulation.

[0047] In preferred embodiments of the invention, the contraceptive-effective and hormone-replacement-effective amounts of E2 and P4 are those suitable for achieving the desired effect in a female human, and, on a unit dose basis are about 5 mg to about 15 mg estradiol and about 300 mg to about 500 mg progesterone. More preferred embodiments comprise about 9 mg 17-β-estradiol and about 400 mg progesterone.

[0048] The formulation of the present invention comprises hormone-containing microspheres to provide controlled, predictable and reproducible administration of the hormones contained therein. Various physicochemical characteristics of the microspheres are important to achieving controlled release of the hormones. In particular, solubility, size and polymorphic composition of the microspheres have a substantial effect on the rate of release. For instance, the greater the diameter of the microsphere, the longer it takes for the hormone level to reach undetectable values. In the present invention, the diameter of the microspheres is preferably about 25 μm to about 125 μm; more preferably about 35 μm to about 105 μm; and most preferably about 35 μm to about 75 μm.
[0049] As the natural hormones E2 and P4 are known to metabolically degrade when administered orally, the formulation of the present invention is preferably administered to subjects by parenteral administration, particularly intramuscular injection. The goal is to provide a contraceptive effect while simultaneously providing a hormone-replacement effect by supplying natural levels of E2 and P4. Further, the formulations of the present invention promote the establishment of healthy monthly menstrual cycles of about 28 days V 3 days. In preferred embodiments, the formulations of the present invention are administered to a subject by injection on a monthly basis using a suitable means of injection such as, for example, an 18 or 20 gauge hypodermic needle.

[0050] Formulations of the instant invention comprise contraceptive-effective and hormone-replacement-effective amounts of an estrogen (E2) and a progestin (P4) compounded in a prolonged or delayed release formulation. Such delayed release formulations can include the estrogen and progestin compounded with a carrier, excipient, or binder having reduced solubility in the biological fluids at the site of administration, such as cholesterol. Cholesterol has substantially less solubility in biological fluids such as blood as compared to estrogens and progestins, and thereby diminishes the dissolution of those active agents, and thereby delays the release of those active agents into the bloodstream. Additional information that might be instructive in the preparation of such delayed release microsphere formulations is found in U.S. Patent Nos. 5,360,616; 5,512,303; 5,633,014; 5,643,604; and 6,287,693.

[0051] In at least one preferred embodiment, a delayed-release formulation of the present invention is prepared by mixing the estrogen thoroughly and uniformly throughout a cholesterol carrier. The estrogen/progestin/cholesterol mixture can be melt congealed and/or extruded or otherwise processed into a plurality of particles of desired size and shape, and subjected to a solid state crystallization as disclosed in U.S. Patent No. 6,287,693. The ‘693 patent discloses a solid state crystallization process whereby a composition of mixed morphologies is formed into particles of desired size and shape, and subsequently crystallized to the most stable polymorph of each of the respective constituents without loss of the particle’s size/shape characteristics by exposing the particles to an environment having a high atmospheric concentration of one or more solvents. The resulting shaped crystalline particles are storage stable, that is they can be packaged and stored as a dry solid or powder or as a suspension in an aqueous vehicle for extended periods (e.g., at least about one month) without loss of the desired size/shape characteristics. Because the solid state crystallization process affords high purity and stability, the particles of the present invention can be fabricated with or without additional excipients, buffers, stabilizers, preservatives, and biocides.

[0052] The ability to fabricate particles of desired size and shape is particularly advantageous as it provides a means for ensuring consistent or even uniform particle size and shape, which in turn ensures ease of administration (e.g., via hypodermic syringe), and controlled and predictable dissolution and release of the active agent(s). In particularly preferred embodiments, the particles are microspheres.

[0053] The formulations of the present invention may be administered by any conventional route of administration. The preferred route of administration is parenteral administration, and a more preferred route is by intramuscular (IM) injection. When administered by parenteral administration, it is preferred that the formulation be compounded as a fluid, whether in solution or as a mixture such as a suspension. Preferably, the formulation comprises the microspheres discussed above as a suspension in an aqueous vehicle.

[0054] Optionally, the formulation can be compounded as a powder for subsequent admixture with a carrier and administration. In such embodiments, the formulation can be packaged and commercialized as part of a kit. Such a kit might comprise unit or multiple doses of: (1) a powder comprising the active agents in combination with excipients, additives, buffers, preservatives, and the like; (2) unit or multiple dose quantities of a fluid carrier, optionally comprising buffers, preservatives, and/or biocides; and (3) an injection device such as a hypodermic syringe, preferably about an 18 or 20 gauge syringe.

[0055] Still another option for the administration of the formulations of the present invention is transdermal delivery. Transdermal delivery of drugs can be effected by various means including injection of a powder as by a biologic method wherein particles are accelerated by a gas or other means to pass through the skin. An example of such an approach is described in U.S. Patent Nos. 6,168,597, entitled "Needleless syringe using supersonic gas flow for particle delivery"; and 6,475,181, entitled Drug Particle Delivery.

[0056] Similarly transdermal delivery can be achieved more passively as by adhesive patches applied to the skin for extended periods. Such patches are described in, e.g., U.S. Patent No. 6,149,935, entitled "Solid matrix system for transdermal drug delivery".

[0057] The formulations of the present invention can be effectively administered to any mammalian organism such as a primate, canine, feline, ovine, equine, porcine, bovine, or murine organism. Preferably, the subject is a primate organism, and still more
preferably is a female human. It will be understood that the particular estrogen and progestin utilized in formulations for different mammals may vary, as will the quantities.

[0058] The microsphere-containing formulation of the present invention can be prepared using any suitable method. In one preferred embodiment, the microspheres are prepared by heating E2 and/or P4 and then rapidly cooling so that the microspheres become sufficiently crystallized. Subsequent to crystallization, the capsules can be collected by filtration on a particle-size basis.

[0059] Generally, the larger-sized microspheres decrease the maximum concentration of the hormones and the time required to reach that concentration. Additionally, larger-sized microspheres increase the hormone absorption half-life.

[0060] Also described herein is a kit for use in contraceptive/hormone-replacement therapy. The kit can comprise a formulation according to the invention, which comprises a contraceptive-effective and a hormone-replacement-effective amount of 17-β-estradiol and progesterone. The kit can further comprise one or more additional components such as a sterile ampule comprising an aqueous vehicle for reconstituting the formulation into a homogeneous suspension, if the formulation is provided in microspheres in sterile powder form. Further, the kit can include means for administering the formulation such as, for example, syringes with 18 and/or 20 gauge needles for intramuscular injection.

[0061] It is contemplated that the compositions of the present invention can be formulated and administered in accordance with the following protocol. A microsphere formulation comprising 9 mg of E2/400 mg P4 is prepared as a sterile powder wherein the microspheres range in size from about 35 μm to about 75 μm, preferably about 39 μm to about 52 μm. In certain preferred embodiments, the powder is packaged dry in unit dose syringes. Preferred are syringes of about 18 or 20 gauge needles for intramuscular injection. The syringes are preferably packaged in air-tight, sterile packaging, and stored under ambient conditions at about 15EC to about 30EC.

[0062] The pre-packaged powder formulation can be suspended in an aqueous vehicle. In a preferred embodiment, the aqueous vehicle is taken from a sterile ampule containing 3.0 ml of an aqueous vehicle. A preferred aqueous vehicle used to suspend the microspheres is composed of:

One of ordinary skill in the art will understand that the composition and relative concentrations of such an aqueous vehicle are not critical to the present invention, and thus both can be varied without substantially altering or diminishing the advantages or utility of the present invention.

[0063] Reconstitution can be effected by vigorous agitation until a homogenous suspension is obtained. The resulting suspension is preferably administered by deep intramuscular injection, e.g., in the gluteal region. The first dose should be given in the first five days from the start of the last menstruation. Subsequent doses are to be administered on a schedule of every 28 V 3 days. For ease and comfort, the subsequent doses can be administered in alternating gluteal regions.

[0064] A pharmaceutical formulation comprising microspheres of progesterone and microspheres of estradiol and cholesterol produced a reliable contraceptive effect. See Example 1, Test article B, below. A recognized shortcoming of estradiol-containing parenteral contraceptive formulations is its high solubility in aqueous solutions. Estradiol-containing microspheres can be formulated by post-fabrication treatment or tempering of the microspheres. That is, the microspheres are first formed into the desired size and shape, subjected to a treatment or tempering step in a controlled atmosphere, and then dried and/or recovered. Depending on the treatment, the EC microspheres have an estradiol dissolution rate in aqueous solution over 24 hours of about 20% or less, and preferably about 15% or less. More preferred embodiments afford dissolution rates of about 10% or less; and still more preferred are those having an estradiol dissolution rate of about 6% or less.

[0065] The estradiol dissolution rate (EDR) is a measure of the quantity of estradiol dissolved in an aqueous solution of 0.3% w/v polyoxyethylenesorbitan monooctadecyl (Tween 80®) in USP purified water for 24 hours at 37°C and standard pressure.

[0066] The production of particles having low EDR facilitates the preparation of a pharmaceutical formulation for hormone
replacement therapy (HRT) containing very low concentration of estradiol. Such low estradiol-concentration compositions are well suited to patients in need of HRT during the first five years of menopause. Further, formulations having low EDR facilitate a treatment regimen involving fewer, or lower frequency, courses of administration. It is contemplated that the formulations of this invention can be administered as infrequently as monthly or every other month.

[0067] X-ray diffraction studies of the particles demonstrating such low rates of estradiol dissolution suggest that the particles are molecular aggregates with a hemocrystalline composition comprising both an amorphous and a crystalline component. Low EDR compositions are those wherein the estradiol consists of about 45% to about 85% amorphous component, and about 35% to about 55% crystalline component. Preferably, the particles are about 50-60% amorphous component and about 40-50% crystalline component. More preferably, the particles are about 55% amorphous component and about 45% crystalline component. These low EDR compositions are preferably formulated from a mixture of a 1:1 molar ratio of estradiol:cholesterol.

[0068] Without wishing to be bound by any theory or scientific principle, applicants believe that the reduced solubility and lower dissolution profile is attributable to the orientation of the amorphous component and the crystalline component within the molecular aggregate or molecular composite. That is, it is contemplated that the exterior surface of the particle is comprised predominantly of the amorphous component such that the molecules of estradiol orient a predominantly hydrophobic portion of the molecule toward the solvent thus making the particles substantially insoluble in water.

[0069] Slow release estradiol particles can be formulated by compounding estradiol and cholesterol in a 1:1 molar ratio, fabricating the composition into particles of the desired size and shape, and subjecting them to a solvent-saturated atmosphere for an extended period at elevated temperature, and subsequently, drying the particles at elevated temperature. In one embodiment, the fabricated particles are exposed to an atmosphere of low relative humidity (RH) for about 12 hours or more prior to exposure to the solvent-saturated atmosphere. Preferably, the particles are formulated as microspheres.

[0070] Microspheres having an EDR of about 15% or less can be formulated by: creating particles consisting essentially of a 1:1 molar ratio of estradiol and cholesterol wherein either or both are in an amorphous or polymorphous form; exposing the particles to an atmosphere of about 25% relative humidity (RH) or less for at least about 12 hours; exposing the particles to an atmosphere saturated with acetone and water for at least about 48 hours at about 50°C to about 65°C; drying the particles at about 35°C to about 50°C for about 24 hours or more; and recovering said particles; wherein the EDR from the recovered particles is less than about 15% (by weight) over 24 hours.

[0071] More preferably, the method involves creating particles consisting essentially of estradiol and cholesterol wherein either or both are in an amorphous or polymorphous form; exposing said particles to an atmosphere of low RH for about 24 hours; exposing the particles to an atmosphere saturated with acetone and water for about 72 hours at about 60°C; drying the particles at about 45°C for about 42 hours; and recovering said particles; wherein the estradiol dissolution rate from the recovered particles in aqueous solution is less than about 6% (by weight) over 24 hours.

[0072] The relative concentrations of acetone and water saturating the atmosphere are about 65 mole % to about 80 mole %, and about 20 mole % to about 35 mole %, respectively. Preferably, the relative concentrations are about 70 mole % to about 75 mole % acetone; and about 25 mole % to about 30 mole %, water. Most preferably, the concentrations of the two components are about 72 mole % acetone to about 28 mole % water. The low relative humidity environment is about 25% RH or less; and preferably, about 20% or less.

[0073] Alternatively, particles having an EDR of about 20% or less can be formulated by serial exposure to an acetone/water-containing atmosphere, and to an ethanol/water-containing atmosphere. That method involves: (a) creating particles consisting essentially of estradiol and cholesterol in about a 1.1 molar ratio wherein either or both are in an amorphous or polymorphous form; (b) exposing said particles to an atmosphere saturated with acetone and water; (c) repeating step (b) at least once, and preferably twice; (d) exposing said particles to an atmosphere saturated with ethanol and water; (e) drying the particles; and (f) recovering said particles; wherein the estradiol dissolution rate from the recovered particles in aqueous solution is less than about 20% (by weight) over 24 hours.

[0074] In preferred embodiments, particles are exposed to vapors of an acetone/water mixture for about two to about five consecutive stages of at least about 12 hours at about 20°C - 40°C. Preferably, the acetone/water stage is conducted in three consecutive stages over about 24 hours at about 30°C.

[0075] The relative concentration of the acetone/water mixture is as described above, and the ethanol/water mixture is a relative concentration of about 95 mole % to about 99 mole % ethanol; and about 5 mole % to about 1 mole % water. The particles can be dried at about 40°C to about 50°C, preferably about 45°C, for about 24 hours or more, and preferably about 36 hours. The drying
stages described here and above can be conducted under vacuum or in air.

[0076] More preferably, the alternative method involves: creating particles consisting essentially of estradiol and cholesterol in about a 1:1 molar ratio wherein either or both are in an amorphous or polymorphous form; exposing said particles to an atmosphere saturated with acetone and water at about 30°C for three consecutive stages of about 24 hours; exposing said particles to an atmosphere saturated with ethanol and water for about two hours at about 30°C; drying the particles at about 45°C for about 42 hours; and recovering said particles; wherein the estradiol dissolution rate from the recovered particles in aqueous solution is less than about 20% (by weight) over 24 hours.

[0077] The methods above afford means for fabricating microspheres of estradiol and cholesterol having an EDR less than about 20% (by weight). Preferred embodiments have an EDR of about 15% or less, and more preferably about 6% or less. The estradiol of the microspheres in a formulation of the present invention is in a hemihydrate or composite form where about 50-60% is amorphous and about 40-50% is crystalline. Preferred embodiments are those wherein the estradiol is about 55% is amorphous and about 45% is crystalline.

[0078] The low EDR estradiol/cholesterol particles of the foregoing methods can be combined with progesterone to make low dose estradiol formulations that can be administered monthly or less often. For example, the invention affords a pharmaceutical formulation comprising about 5 to about 15 mg 17-β-estradiol admixed with cholesterol in about a 1:1 molar ratio, and about 300 to about 400 mg progesterone; wherein the weight ratio of 17-β-estradiol to progesterone is about 1:40, the 17-β-estradiol consists of a hemihydrate form that is about 50-60% amorphous and about 40-50% crystalline, and the EDR of the formulation is about 20% or less. The formulation can be prepared of particles of estradiol/cholesterol in combination with particles of progesterone. The particles are preferably microspheres. The particles can further include additives and excipients, such as lubricants, buffers, stabilizers, and the like. Additionally, the particles can be suspended in a carrier for parenteral administration. Those formulations have a contraceptive effect and can be used effectively in hormone replacement regimens involving parenteral administration once a month or every other month. Preferably, the formulation is administered by intramuscular injection.

**EXAMPLE 1**

**PHARMACOKINETIC STUDY IN RABBITS TO ASSESS THE BIOAVAILABILITY OF DIFFERENT COMBINATIONS OF PROGESTERONE MICROSPHERES & ESTRADIOL MICROSPHERES AND MICROSPHERES AT DIFFERENT RATIOS OF ESTRADIOL TO CHOLESTEROL**

[0079] This study is aimed at assessing the pharmacokinetic profile of test articles containing Progesterone (P) and 17-β-Estradiol (E). A prospective and comparative study was conducted in New Zealand male rabbits. Test articles consisted of aqueous suspensions using the aqueous vehicle described above of microspheres of progesterone + microspheres of estradiol (E) or estradiol cholesterol (EC), manufactured by following the process described in US Patent No 5,360,616 and crystallized according to US Patent No. 6,528,094 B1. Test articles evaluated are the following:

<table>
<thead>

</tbody>
</table>

[0080] The aqueous suspensions were administered in the form of intramuscular (IM) injections. Each rabbit received 133 mg of progesterone and 3 mg of estradiol. Blood samples were collected at time 0 (predose), 1, 2, 4 and 9 hours, and every day from day 2 to 14, and every other day from day 14 to 28. The resulting samples were assayed for progesterone and estradiol by radioimmunoassay (RIA).

[0081] From the plasma profiles, the following pharmacokinetic parameters were calculated: Area Under the Curve to infinite (AUC_\(\text{INF}\)), Area Under the Curve to the last sampling time (AUCO–t), Maximum plasma concentration (C_{max}), time to reach the C_{max}(T_{max}), Half-life (t_1/2), Elimination Constant (K_e), and Mean Residence Time (MRT). These results were analyzed statistically.
aimed at assessing any possible difference among groups.

[0082] Regarding the comparison of the parameters calculated for Estradiol, although the analysis showed no evidence of any possible statistically significant differences (p<0.05) in these parameters among the groups, as shown in the following table, there are differences in the MRT among the groups since the MRT for (1:1) EC ME (Test Article B) was almost twice longer than for E Microspheres (Test Article A), as seen in the following table:

<table>
<thead>
<tr>
<th>MRT (days)</th>

<td>4</td>
</tr>
</tbody>
</table>

[0083] Regarding the comparison of the parameters calculated for Progesterone although variability was observed in the parameters calculated, no statistically significant difference (p<0.05) was found among groups.

**Graphical Analysis:**

[0084] Mean plasma profiles for Estradiol and Progesterone for the four test articles evaluated are shown in Figures 1 and 2. According to results for estradiol and progesterone, although the statistical analysis showed no evidence of difference between groups, the graphic analysis of plasma profiles (See Figure 1) showed different behavior. This may be attributable to the small sample size.

**EXAMPLE 2 (COMPARATIVE)**

**Microspheres of a Mixture of 49%17-β-estradiol and 51%cholesterol**

[0085] This comparative example is analogous to the fabrication of particles according to Example 7 of U.S. Patent No. 6,528,094 B1 (also referred to herein as "Crystallization Process A"). The estradiol/cholesterol microspheres can be combined with progesterone microspheres to produce the pharmaceutical formulation of Test Article B of Example 1, above.

[0086] The microspheres of this mixture were obtained by melting together the components and, as for the pure substances, sprayed into droplets and congealed into microspheres. The microspheres initially showed a high amorphous content.

[0087] When the microspheres were placed in a recipient of approximately 7 liters and exposed for 24 hours at 30°C. to the vapors of 8 mL of ethanol kept in a porous cellulose material, the initially amorphous microspheres crystallized completely in the presence of the vapors.

[0088] The microspheres were dried at 60°C in a vacuum for 24 hours, and residual ethanol present in the microspheres was less than 0.01 %.

[0089] To evaluate the stability of the microspheres, non-crystallized microspheres (melt-congealed only) and microspheres according to the present invention were separately placed in aqueous solution at 40°C, and observed by optical microscopy after 82 days. As observed by optical microscopy, the microspheres crystallized according to the present invention remained stable over time when placed in water, whereas the non-crystallized microspheres did not.

[0090] The resulting crystallized microspheres were morphologically stable for 82 days when placed in a solution of 0.01 % Polysorbate 80 in USP purified water at 40°C, or for 14 days when they were injected intramuscularly into rabbits.

[0091] Figure 3 shows the X-ray diffractogram of the EC (40:60) Microspheres before and after crystallization, and Figure 4 shows the corresponding dissolution profile (i.e., 74% of estradiol dissolved at 24 hours in an aqueous solution of 0.3% Tween 80®).
EXAMPLE 3

Modified Crystallization Process for EC ME Presenting 20% Dissolution Over 24 Hours ("Crystallization Process B")

[0092] Estradiol-cholesterol (1:1) microspheres were fabricated as in Example 2, above. The microspheres, having a high amorphous content, were exposed to vapors of acetone and water (95 mole % acetone: 5 mole % water) for three consecutive 24 hour stages at 30°C. Between stages, hermetic containers are opened and the contents dried with air, residual solvent is removed and then the estradiol microspheres are submitted to the next vapor-exposure stage.

[0093] The particles were then heated (desiccated) at 45°C for 42 hours under vacuum (about 12.2 in. Hg).

[0094] The resulting particles produced an average EDR of about 20%. See Figure 5.

EXAMPLE 4

Crystallization Process for Ultralow Dissolution of Estradiol-Cholesterol Microspheres ("Crystallization Process C")

[0095] Estradiol-cholesterol microspheres were fabricated according to the process of Example 2. The particles were stored under low relative humidity for 24 hours. The particles were then exposed to vapors of acetone and water (72 mole % acetone/28 mole % water) for 72 hours at 60°C. The particles were then heated (for desiccation) at 45°C for 42 hours.

[0096] The resulting particles had an average of about 5% dissolution of estradiol over 24 hours in an aqueous solution of 0.3% polyoxyethylene sorbitan monolaurate (Tween 80®) at standard temperature and pressure.

[0097] Figure 19 illustrates the dissolution profile of the particles of this Example compared to those resulting from the methods of Examples 2 and 3.

[0098] Figure 20 shows the DSC profile of the particles resulting from this Example.

[0099] Figures 21 and 22 are X-ray diffractograms of the particles resulting from Example 4.

PATENTKRAV

1. Formulering, som har præventions- og hormonerstatningsvirkninger i et hunpattedyr og omfatter mikrosfærer af 17-β-estradiol og cholesterol og mikrosfærer af progesteron, hvor 17-β-estradiol er 45 til 65% amorf og 35 til 55% kristallinsk, og hvor formuleringen har en estradiolopløsningsrate (EDR) på 20% eller mindre.

2. Formulering ifølge krav 1, hvor EDR er 10% eller mindre.

3. Formulering ifølge krav 1, hvor EDR er 6% eller mindre.

4. Formulering ifølge krav 1, som omfatter 5 til 15 mg 17-β-estradiol og 200 til 500 mg progesteron.

5. Formulering ifølge krav 1, som omfatter 5 til 15 mg 17-β-estradiol og 300 til 500 mg progesteron.

6. Formulering ifølge krav 1, hvor 17-β-estradiol og cholesterol er i blanding i et 1:1 molært forhold.

7. Formulering ifølge krav 1, hvor vægtforholdet mellem 17-β-estradiol og progesteron er 1:40.

8. Formulering ifølge krav 1, hvor vægtforholdet mellem 17-β-estradiol og progesteron er 9:400.

9. Formulering ifølge krav 1, hvor 17-β-estradiol er 50 til 60% amorf og 40 til 50% kristallinsk.

10. Formulering ifølge krav 1, hvor 17-β-estradiol er 55% amorf og 45% kristallinsk.

11. Formulering ifølge krav 1, som er formuleret til administration ved intramuskulær injektion.
12. Formulering ifølge krav 1, hvor mikrosfærerne af 17-β-estradiol og cholesterol og mikrosfærerne af progesteron har diametre på mellem 25 μm og 125 μm.

13. Formulering ifølge krav 1, hvor mikrosfærerne af 17-β-estradiol og cholesterol og mikrosfærerne af progesteron har diametre på mellem 35 μm og 75 μm.

14. Formulering, som omfatter partikler af 17-β-estradiol og cholesterol og partikler af progesteron, og hvor 17-β-estradiol og progesteron er i et vægtforhold på 3:40 til 1:100, og hvor 17-β-estradiol er 45 til 65% amorf og 35 til 55% krystallinsk, og hvor formuleringen har en estradiolopløsningsrate (EDR) på 20% eller mindre, til anvendelse til prævention i et hunnpatedyr.

15. Formulering til anvendelse til prævention i et hunnpatedyr ifølge krav 14, hvor formuleringen er formuleret til gentagen administration efter én komplet menstruationscyklus hos individet.

16. Formulering til anvendelse til prævention i et hunnpatedyr ifølge krav 14, hvor formuleringen er formuleret til administration ved intramuskulær injektion.

17. Formulering til anvendelse til prævention i et hunnpatedyr ifølge krav 14, hvor partiklerne i formuleringen er mikrosfærer, som har en diameter på mellem 35 μm og 75 μm.

18. Formulering til anvendelse til prævention i et hunnpatedyr ifølge krav 14, hvor vægtforholdet mellem 17-β-estradiol og progesteron er 1:40.

20. Formulering til anvendelse til prævention i et hunnpatedyr ifølge krav 14, hvor 17-β-estradiol er 50-60% amorf og 40-50% krystallinsk.

21. Formulering til anvendelse til prævention i et hunnpatedyr ifølge krav 20, hvor formuleringen har en EDR på 10% eller mindre.
22. Formulering til anvendelse til prævention i et hunpattedyr ifølge krav 20, hvor formuleringen har en EDR på 6% eller mindre.

23. Formulering til anvendelse til prævention i et hunpattedyr ifølge krav 20, hvor formuleringen omfatter 5 til 15 mg 17-β-estradiol og 300 til 500 mg progesteron.

24. Formulering til anvendelse til prævention i et hunpattedyr ifølge krav 20, hvor 17-β-estradiol i formuleringen er 55% amorf og 45% krystallinsk.

25. Formulering til anvendelse til prævention i et hunpattedyr ifølge krav 20, hvor formuleringen er formuleret til administration ved intramuskulær injektion.

26. Formulering til anvendelse til prævention i et hunpattedyr ifølge krav 20, hvor formuleringen er formuleret til administration én gang om måneden eller mindre hyppigt.

27. Formulering til anvendelse til prævention i et hunpattedyr ifølge krav 20, hvor formuleringen er formuleret til administration én gang hver anden måned.

28. Formulering til anvendelse til prævention i et hunpattedyr ifølge krav 20, hvor pattedyret er et menneske.

29. Formulering til anvendelse til prævention i et hunpattedyr ifølge krav 20, hvor 17-β-estradiol og cholesterol er i blanding i et 1:1 molært forhold.

30. Formulering til anvendelse til prævention i et hunpattedyr ifølge krav 20, hvor vægtforholdet mellem 17-β-estradiol og progesteron er 1:40.

31. Formulering til anvendelse til prævention i et hunpattedyr ifølge krav 20, hvor vægtforholdet mellem 17-β-estradiol og progesteron er 9:400.

32. Formulering til anvendelse til prævention i et hunpattedyr ifølge krav 20, hvor partiklerne af 17-β-estradiol og cholesterol og partiklerne af progesteron har diametre på mellem 25 μm og 125 μm.
33. Formulering ifølge et hvilket som helst af kravene 1 til 13 til anvendelse til prævention i et hunpattedyr.

34. Formulering ifølge et hvilket som helst af kravene 1 til 13 til anvendelse til hormon-erstatningsterapi i et hunpattedyr i de første fem år af menopausen.
