Description

Background of the Invention

The invention relates generally to sound reproduction. More specifically, the invention relates to multiple channel sound reproduction systems having improved listener perceived characteristics.

Multiple channel sound reproduction systems which include a surround-sound channel (often referred to in the past as an "ambience" or "special-effects" channel) in addition to left and right (and optimally, center) sound channels are now relatively common in motion picture theaters and are becoming more and more common in the homes of consumers. A driving force behind the proliferation of such systems in consumers' homes is the widespread availability of surround-sound home video software, mainly surround-sound motion pictures (movies) made for theatrical release and subsequently transferred to home video formats (e.g., videocassettes and videodiscs).

Although home video software formats have two-channel stereophonic soundtracks, those two channels carry, by means of amplitude and phase matrix encoding, four channels of sound information--left, center, right, and surround, usually identical to the two-channel stereophonic motion-picture soundtracks from which the home video soundtracks are derived. As is also done in the motion picture theater, the left, center, right, and surround channels are decoded and recovered by consumers with a matrix decoder, usually referred to as a "surround-sound" decoder. In the home environment, the decoder is usually incorporated in or is an accessory to a videocassette player, videodisc player, or television set/video monitor. Although nearly universal in motion picture theater environments, the center channel playback is often omitted in home systems. A phantom-image center channel is then fed to left and right loudspeakers to make up for the lack of a center channel speaker.

Motion picture theaters equipped for surround sound typically have at least three sets of loudspeakers, located appropriately for reproduction of the left, center, and right channels, at the front of the theater auditorium, behind the screen. The surround channel is usually applied to a multiplicity of speakers located other than at the front of the theater auditorium.

It is the recommended and common practice in the industry to align the sound system of large auditoriums, particularly a motion picture theater's loudspeaker-room response, to a standardized frequency response curve or "house curve." The current standardized house curve for movie theaters is a recommendation of the International Standards Organization designated as curve X of ISO 2969-1977(E). The use of a standardized response curve is significant because in the final steps of creating motion picture soundtracks, the soundtracks are almost always monitored in large (theater-sized) auditoriums ("mixing" and "dubbing" theaters) whose loudspeaker-room responses have been aligned to the standardized response curve. This is done, of course, with the expectation that such motion picture films will be played in large (theater-sized) auditoriums that have been aligned to the same standardized response curve. Consequently, motion picture soundtracks inherently carry a built-in equalization that takes into account or compensates for playback in large (theater-sized) auditoriums whose loudspeaker-room responses are aligned to the standardized curve.

The current standardized curve, curve X of ISO 2969, is a curve having a significant high-frequency rolloff. The curve is the result of subjective listening tests conducted in large (theater-sized) auditoriums. A basic rationale for such a curve is given by Robert B. Schulein in his article "In Situ Measurement and Equalization of Sound Reproduction Systems," J. Audio Eng. Soc., April 1975, Vol. 23, No. 3, pp. 178-186. Schulein explains that the requirement for high-frequency rolloff is apparently due to the free fold (i.e., direct) to diffuse (i.e., reflected or reverberant) sound field diffraction effects of the human head and ears. A distant loudspeaker in a large listening room is perceived by listeners as having greater high frequency output than a closer loudspeaker, if aligned to measure the same response. This appears to be a result of the substantial diffuse field to free field ratio generated by the distant loudspeaker; a loudspeaker close to a listener generates such a small diffuse to direct sound ratio as to be insignificant.

More recently the rationale has been carried further by Gunther Theile ("On the Standardization of the Frequency Response of High-Quality Studio Headphones," J. Audio Eng. Soc., December 1986, Vol. 34, No. 12, pp. 956-969) who hypothesized that perceptions of loudness and tone color (timbre) are not completely determined by sound pressure and spectrum in the auditory canal. Theile relates this hypothesis to the "source location effect" or "sound level loudness divergence" ("SLD") which occurs whenever auditory events with differing locations are compared: a nearer loudspeaker requires more sound level (sound pressure) at the ear drums to cause the same perceived sound loudness as a more distant loudspeaker and the effect is frequency dependent.

It has also been recognized that the sound pressure level in a free direct field exceeds that in a diffuse field for equal loudness. A standard equalization, currently embodied in ISO 454-1975 (E) of the International Standards Organization, is intended to compensate for the differences in perceived loudness and, by exten-

sion, timbre due to frequency response changes between such sound fields.

Perceived sound loudness and timbre thus depends not only on the location at which sound fields are generated with respect to the listener but also on the relative diffuse (reflected or reverberant) field component to free (direct) field component ratio of the sound field at the listener.

One major difference between the home listening environment and the motion picture theater listening environment is in the relative sizes of the listening rooms--the typical home listening room, of course, being much smaller. While there is no established standard curve to which home sound systems are aligned, the high-frequency rolloff house curve applicable to large auditoriums is not applicable to the considerably smaller home listening room because of the above-mentioned effects.

Unlike home video software media having soundtracks transferred from motion picture film soundtracks, recorded consumer software sound media (e.g., vinyl phonograph records, cassette tapes, compact discs, etc.) have a built-in equalization that compensates for typical home listening room environments. This is because during their preparation such recordings are monitored in relatively small (home listening room sized) monitoring studios using loudspeakers which are the same or similar to those typically used in homes. Relative to large auditorium theater environments, the response of a typical modern home listening room-loudspeaker system or a small studio listening room-loudspeaker system can be characterized as substantially "flat," particularly in the high-frequency region in which rolloff is applied in the large auditorium house curve. A consequence of these differences is that motion pictures transferred to home video software media have too much high-frequency sound when reproduced by a home system. Consequently, the musical portions of motion picture soundtracks played on home systems tend to sound "bright." In addition, other undesirable results occur--"Foley" sound effects, such as the rustling of clothing, etc., which tend to have substantial high-frequency content, are over-emphasized. Also, the increased high-frequency sensitivity of home systems often reveals details in the makeup of the soundtrack that are not intended to be heard by listeners; for example, changes in soundtrack noise level as dialog tracks are cut in and out. These same problems, of course, occur when a motion picture soundtrack is played back in any small listening environment having consumer-type loudspeakers, such as small monitoring studios.

There is yet another difference between the home sound systems and motion picture theater sound systems that detracts from creating a theater-like experience in the home. It has been the practice at least in certain high-quality theater sound systems to employ loudspeakers that provide a substantially directional sound field for the left, center, and right channels and to employ loudspeakers that provide a substantially non-directional sound field for the surround channel. Such an arrangement enhances the perception of sound localization as a result of the directional front loudspeakers while at the same time enhancing the perception of ambience and envelopement as a result of the non-directional surround loudspeakers.

In contrast, home systems typically employ main channel (left and right channel) loudspeakers designed to generate a compromise sound field that is neither extremely directional nor extremely non-directional. Surround channel loudspeakers in the home are usually down-sized versions of the main channel loudspeakers and generate similar sound fields. In the home environment, little or no attention has been given to the proper selection of directional characteristics for the main channel and surround channel speakers.

Also, with respect even to the above-mentioned high-quality theater sound systems, no compensation has been employed for the differences in listener perceived timbre between the main channels and the surround channel resulting from the generation of predominantly direct sound fields by the main channel speakers and the predominantly diffuse sound field produced by the surround channel speakers.

In addition, with respect to home systems and to the above-mentioned high quality theater sound systems, a single (monophonic) surround-sound channel is applied to multiple loudspeakers (usually two, in the case of the home, located to the left and right rear of home listening room and usually more than two, in the case of a motion-picture theater, located on the side and rear walls). Particularly in the home environment, the result is that the surround-sound channel sounds to a listener seated on the center line as though it were in the middle of the head.

The document EP-A-0 249 640 discloses a multi-channel stereo reproducing apparatus receiving left, center, right and rear channel signals encoded as left total and right total signals. The left total and the right total signal are supplied to a balancing circuit outputting balanced left total and right total signals. The balanced signals are supplied through amplifiers 4 and 5 to left and right front loud-speakers, respectively. The left total and the right total signal are further applied to a mixing circuit generating at its output the sum signal of the left total and the right total signals, the sum signal being applied through an amplifier to a center front loud-speaker. The balanced total signals are also applied to a subtracting circuit generating at its output the difference signal between the left total and the right total signals. The difference signal is applied through a delay circuit, a low-pass filter and a de-emphasis circuit to left and right rear loudspeakers. The de-emphasis circuit is for compensating for a pre-emphasis which in some cases is applied to the original rear signal. A switch is

provided for bypassing the de-emphasis circuit allowing the reproducing apparatus to be used also for reproducing sound from a recording medium having a simple two-channel stereo signal comprising only a left front signal and a right front signal recording on it.

Summary of the Invention

Aspects of the present invention are directed primarily to surround-sound reproduction systems in relatively small listening rooms, particularly those in homes. With respect to such, the invention solves the problem of spectral imbalance (e.g., alteration in timbre), particularly excessive high-frequency energy, when playing pre-recorded sound material that is equalized for playback in a large (theater-sized) auditorium whose room-loudspeaker system is aligned to a frequency response curve having a significant high-frequency rolloff. In a preferred embodiment, re-equalization according to a correction curve is provided in the playback system in order to restore to a "flat" response the perceived spectral balance of recordings transferred from motion picture soundtracks having an inherent high-frequency boost because of their intended playback in large (theater-sized) auditoriums aligned to the standard house curve. Such re-equalization restores the spectral distribution (timbre) intended by the creators of the pre-recorded sound material.

With respect to small (home-sized) listening rooms, a further aspect of the invention is to generate generally directional sound fields in response to the left and right sound channels and in response to the center sound channel, if used, and to generate a generally non-directional sound field in response to the surround-sound channel.

A directional sound field is one in which the free (direct) component of the sound field is predominant over the diffuse component at listening positions within the listening room. A non-directional sound field is one in which the diffuse component of the sound field is predominant over the free (direct) component at listening positions within the listening room. Directionality of a sound field depends at least on the Q of the loudspeaker or loudspeakers producing the sound field ("Q" is a measure of the directional properties of a loudspeaker), the number of loudspeakers, the size and characteristics of the listening room, the manner in which the loudspeaker (or loudspeakers) is (or are) acoustically coupled to (e.g., positioned with respect to) the listening room, and the listening position within the room. For example, multiple high Q (directional) loudspeakers can be distributed so as to produce a non-directional sound field within a room. Also, the directionality of multiple loudspeakers reproducing the same channel of sound can be affected by their physical relationship to one another and differences in amplitude and phase of the signal applied to them.

This aspect of the invention is not concerned per se with specific loudspeakers nor with their acoustic coupling to small listening rooms, but rather it is concerned, in part, with the generation of direct and diffuse sound fields for the main (left, right, and, optionally, center) channels and for the surround channel, respectively, in a small (home-sized) room surround-sound system using whatever combinations of available loudspeakers and techniques as may be required to generate such sound fields. This aspect of the invention recognizes that excellent stereophonic imaging and detail combined with sonic envelopement of the listeners can be achieved not only in large (theater-sized) auditoriums but also in the small (home-sized) listening room by generating generally direct sound fields for the main channels and a generally diffuse sound field for the surround channel. In this way, the home listening experience can more closely re-create the quality theater sound experience.

According to a further aspect of the invention, the listening impression created by the generation of direct sound fields for the main channels and a diffuse sound field for the surround channel can be improved even further, for all sizes of listening rooms, by the addition of equalization to compensate for the differences in perceived timbre between direct and diffuse sound fields. In other words, the full benefit of the use of direct and diffuse sound fields for the main and surround channels, respectively, is not achieved unless appropriate equalization is provided in the surround channel in order to compensate for its reproduction of a diffuse sound field. Although the standard curve ISO 454 is intended to compensate for the frequency dependent differences in perceived loudness between direct and diffuse fields, it has not heretofore been appreciated that such a correction is relevant to surround-sound systems.

According to yet a further aspect of the invention, the listener's impression of the surround-sound channel can be improved, for all sizes of listening rooms, by decreasing the interaural cross-correlation of the surround-sound channel sound field at listening positions within the room. Preferably, this is accomplished by a technique such as slight pitch shifting between multiple surround loudspeakers, which does not cause undesirable side effect. While this aspect of the invention may be employed without the aforementioned generation of generally direct sound fields for the main channels and a generally diffuse sound field for the surround channel, the combination of these aspects of the invention provides an even more psychoacoustically pleasing listening experience. Preferably, the combination further includes the aspect of the invention providing for surround channel equalization to compensate for the listener perceived difference in timbre between a direct sound field and a

4

diffuse sound field.

Brief Description of the Drawings

Figure 1 is a block diagram of a surround-sound reproduction system embodying aspects of the invention.

Figure 2 is a block diagram of a surround-sound reproduction system embodying aspects of the invention.

Figure 3 is a loudspeaker-room response curve used by theaters, curve X of the International Standard ISO 2969-1977(E), extrapolated to 20 kHz.

Figure 4 is a correction curve, according to one aspect of this invention, to compensate for the large room equalization inherent in motion picture soundtracks when played back in small listening rooms.

Figure 5 is a schematic circuit diagram showing the preferred embodiment of a filter/equalizer for implementing the correction curve of Figure 4.

Figure 6 is a diagram in the frequency domain showing the locations of the poles and zeros on the s-plane of the filter/equalizer of Figure 5.

Figure 7 is a schematic circuit diagram showing the preferred embodiment for implementing the surround channel direct/diffuse sound field equalizer according to another aspect of the invention.

Figure 8 is a block diagram showing an arrangement for deriving, by means of pitch shifting, two sound outputs from the surround-sound channel capable of providing, according to another aspect of the invention, sound fields having low-interaural cross-correlation at listening positions.

Detailed Description of the Invention

Figures 1 and 2 show, respectively, block diagrams of two surround sound reproduction systems embodying aspects of the invention. Figures 1 and 2 are generally equivalent, although, for reasons explained below, the arrangement of Figure 2 is preferred. Throughout the specification and drawings, like elements generally are assigned the same reference numerals; similar elements are generally assigned the same reference numerals but are distinguished by prime (') marks.

In both Figures 1 and 2, left (L), center (C), right (R), and surround (S) channels, matrix encoded, according to well-known techniques, as left total (LT) and right total (RT) signals, are applied to decoding and equalization means 2 and 2', respectively. Both decoding and equalization means 2 and 2' include a matrix decoder that is intended to derive the L, C, R, and S channels from the applied LT and RT signals. Such matrix decoders, often referred to as "surround sound" decoders are well-known. Several variations of surround sound decoders are known both for professional motion picture theater use and for consumer home use. For example, the simplest decoders include only a passive matrix, whereas more complex decoders also include a delay line and/or active circuitry in order to enhance channel separation. In addition, many decoders include a noise reduction expander because most matrix encoded motion picture soundtracks employ noise reduction encoding in the surround channel. It is intended that the matrix decoder 4 include all such variations.

In the embodiment of Figure 1, re-equalizer means 6 are placed in the respective LT and RT signal input lines to the matrix decoder 4, whereas in the embodiment of Figure 2, the re-equalizer means 6 are located in the L, C, and R output lines from the matrix decoder 4. The function of the re-equalizer means 6 are explained below. In both the Figure 1 and Figure 2 embodiments, an optional direct/diffuse equalizer means 8 is located in the S output line from the matrix decoder 4. The function of the direct/diffuse equalizer means 8 is also explained below.

In both embodiments, the L, C, R, and S outputs from the decoding and equalization means 2 feed a respective loudspeaker or respective loudspeakers 10, 12, 14, and 16. In home listening environments the center channel loudspeaker 12 is frequently omitted (some matrix decoders intended for home use omit entirely a center channel output). Suitable amplification is provided as necessary, but is not shown for simplicity.

The arrangements of both Figures 1 and 2 thus provide for the coupling of at least the left, right, and surround (and, optionally, the center) sound channels encoded in the LT and RT signals to a respective loudspeaker or loudspeakers. The loudspeakers are intended to be located in operating positions with respect to a listening room in order to generate sound fields responsive to at least the left, right, and surround (and, optionally, the center) channels within the listening room.

Because of the requirement to accurately preserve relative signal phase of the LT and RT input signals for proper operation of the matrix decoder 4, which responds to amplitude and phase relationships in the LT and RT input signals, the placement of the re-equalizing means 6 (a type of filter, as explained below) before the decoder 4, as in the embodiment of Figure 1, is less desirable than the alternative location after the decoder 4 shown in the embodiment of Figure 2. In addition, the re-equalizing means 6, if placed before decoder 4, may affect proper operation of the noise reduction expander, if one is employed, in the matrix decoder 4. The

arrangement of Figure 2 is thus preferred over that of Figure 1. The preferred embodiment of re-equalizer means 6 described below assumes that they are located after the matrix decoder 4 in the manner of the embodiment of Figure 2. If the re-equalizer means 6 are located before the matrix decoder 4 in the manner of Figure 1 it may be necessary to modify their response characteristics in order to minimize effects on noise reduction decoding that may be included in the matrix decoder 4 and, also, it may be necessary to carefully match the characteristics of the two re-equalizer means 6 (of the Figure 1 embodiment) in order to minimize any relative shift in phase and amplitude in the LT and RT signals as they are processed by the re-equalizer means 6.

Figure 3 shows curve X of the International Standard ISO 2969-1977(E) with the response extrapolated to 20 kHz, beyond the official 12.5 kHz upper frequency limit of the standard. It is common practice in many theaters, particularly dubbing theaters and other theaters equipped with high quality surround sound systems, to align their response to an extended X characteristic. The extended X curve is a de facto industry standard. The X characteristic begins to roll off at 2 kHz and is down 7 dB at 10 kHz. The extended curve is down about 9 dB at 16 kHz, the highest frequency employed in current alignment procedures for dubbing theaters. In public motion picture theaters, which are larger than dubbing theaters, the X curve is extended only to 12.5 kHz because the high frequency attenuation of sound in the air becomes a factor above about 12.5 kHz in such large auditoriums. The X curve, and particularly its extension, are believed by some in the industry to be too rolled off at very high frequencies. In contrast to the X curve and the extended X curve, a good quality modern home consumer sound system, although not aligned to a specific standard, tends not to exhibit such a high-frequency room-loudspeaker response roll off. Relative to the X curve and extended X curve, modern home consumer systems may be characterized as relatively flat at high frequencies.

As explained above, in the creation of a motion picture soundtrack, the soundtrack is usually monitored in a theater that has been aligned to the extended X response curve, with the expectation that such motion picture films will be played in theaters that have been aligned to that standardized response curve. Thus, motion picture soundtracks inherently carry a built-in equalization that takes into account or compensates for playback in theater-sized auditoriums whose loudspeaker-room response is aligned to the standardized curve. However, for the reasons discussed above, this built-in equalization is not appropriate for playback in home listening environments: the soundtracks of motion pictures transferred to home video software media have too much high frequency sound energy when reproduced by a home system. Correct timbre is not preserved and details in the soundtrack can be heard that are not intended to be heard.

According to one aspect of this invention, a correction curve is provided to compensate for the large room equalization inherent in motion picture soundtracks when played back in small listening rooms. The correction curve was empirically derived using a specialized commercially-available acoustic testing manikin. The correction curve is a difference curve derived from measurements of steady-state one-third octave sound level spectra taken in representative extended X curve aligned large auditoriums in comparison to a good quality modern home consumer loudspeaker-room sound system. The correction curve is shown in Figure 4 as a cross-hatched band centered about a solid line central response characteristic. The correction band takes into account an allowable tolerance in the correction of about ±1 dB up to about 10 kHz and about ±2 dB from about 10 kHz to 20 kHz, where the ear is less sensitive to variation in response. In practice, the tolerance for the initial flat portion of the characteristic, below about 2 kHz, may be tighter. The form of the correction curve band is generally that of a low-pass filter with a shelving response: the correction is relatively flat up to about 4 to 5 kHz, exhibits a roll off, and again begins to flatten out above about 10 kHz. About 3 to 5 dB roll off is provided at 10 kHz. The extended X curve response is also shown in Figure 4 for reference. As mentioned above, the X curve, and particularly its extension are believed by some in the industry to be too rolled off at very high frequencies. It will be appreciated that the optimum correction curve would change in the event that a modified X curve standard is adopted and put into practice.

A filter/equalizer circuit can be implemented by means of an active filter, such as shown in Figure 5, to provide a transfer characteristic closely approximating the solid central line of the correction curve band of Figure 4. The correct frequency response for the filter/equalizer is obtained by the combination of a simple real pole and a "dip" equalizer section. The real pole is realized by a single RC filter section with a -3dB frequency of 15 kHz. The dip equalizer is a second order filter with a nearly flat response. The transfer function of the section is:

$$\frac{s^2 + \gamma \frac{\omega_o}{Q} + \omega_o^2}{s^2 + \frac{\omega_o}{Q} + \omega_o^2}$$

The complex pole pair and the complex zero pair have the same radian frequency but their angles are slightly

different giving the desired dip in the frequency response with minimum phase shift. The same dip could be achieved with the zeros in the right half plane, but the phase shift would be closer to that of an allpass filter- -180 degrees at the resonant frequency. The parameters of the dip section in the filter/equalizer are:

$$f_o = 12.31 kHz$$

$$Q = 0.81$$

$$\gamma = 0.733$$

where $f_o = 2\pi\omega_o$. Another way of interpreting these parameters is that the Q of the poles is 0.81 and the Q of the zeros is $\dfrac{0.81}{\gamma}$. The dip section can be realized by a single operational amplifier filter stage and six components as shown in Figure 5. The filter stage in effect subtracts a bandpass filtered signal from unity giving the required transfer function and frequency response shape. The circuit topology, one of a class of single operational amplifier biquadratic circuits, is known for use as an allpass filter (Passive and Active Network Analysis and Synthesis by Aram Budak, Houghton Mifflin Company, Boston, 1974, page 451).

The rectangular coordinates of the poles and zeros of the overall filter equalizer are as follows (units are radians/sec in those locations on the s-plane):

Real Pole:

$$\alpha_{rp} = -9.4248x10^4$$

Complex Poles:

$$\alpha_p \pm j\beta_p = -4.7046x10^4 \pm j5.9962x10^4$$

Complex Zeros:

$$\alpha_z \pm j\beta_z = -3.4485x10^4 \pm j6.7967x10^4$$

Figure 6 shows the location of the poles and zeros on the s-plane.

When implemented with the preferred component values listed below, the resulting characteristic response of the filter/equalizer circuit of Figure 5 is:

Frequency, Hz	Response, dB
20	0
100	0
500	0
1,000	0
2,000	−0.2
3,150	−0.4
4,000	−0.7
5,000	−1.1
6,300	−1.8
8,000	−2.8
10,000	−4.2
12,500	−5.2
16,000	−5.4
20,000	−5.7

As mentioned above, there is an allowable tolerance of about ±1 dB up to about 10 kHz and about ±2 dB from about 10 kHz to 20 kHz. The preferred component values of the circuit shown in Figure 5 are as follows:

Component	5% tolerance	1% tolerance
R1	6K8	6K81

(6.81 kilohms)

R2	18K	17K4
C1=C2	1.2N	1.2N (1.2

nanofarads)

RA	2K2	2K00
RB	10K	10K0
RP	4K7	4K87
CP	2.2N	2.2N

The filter/equalizer circuit of Figure 5 is one practical embodiment of the re-equalizer means 6 of Figure 2. Many other filter/equalizer circuit configurations are possible within the teachings of the invention.

Referring again to the embodiments of Figures 1 and 2, the loudspeaker or loudspeakers 10, 12 (if used), and 14 are preferable directional loudspeakers that generate, when in their operating positions in the listening room, left, center (if used), and right channel sound fields in which the free (direct) sound field component is predominant over the diffuse sound field component of each sound field at listening positions within the listening room. The loudspeaker or loudspeakers 16 is (or are) preferably non-directional so as to generate, when in its or their operating positions in the listening room, a surround channel sound field in which the diffuse sound field component is predominant over the free (direct) sound field component at listening positions within the listening room. A non-directional sound field for reproducing the surround channel can be achieved in various ways. Preferably, one or more dipole type loudspeakers each having a generally figure-eight radiation pattern are oriented with one of their respective nulls generally toward the listeners. Other types of loudspeakers having a null in their radiation patterns can also be used. Another possibility is to use a multiplicity of speakers having low directivity arranged around the listeners so as to create an overall sound field that is diffuse. Thus, depending on their placement in the listening room and their orientation with respect to the listening positions, even directional loudspeakers are capable of producing a predominantly diffuse sound field.

In order to obtain the full sonic benefits of directional and non-directional speakers as just set forth, it is preferred that the arrangements of the Figure 1 and Figure 2 embodiments use the optional direct/diffuse equalizer 8. Such an equalizer compensates for the differences in listener perceived timbre between direct and diffuse sound fields. The use of a direct/diffuse equalizer with the directional and non-directional speakers as just set forth is applicable to both large (theater-sized) auditoriums and to small (home) listening rooms. As applied to large (theater-sized) auditoriums, the arrangements of Figures 1 and 2 would, of course, not require the re-equalizer means 6.

The preferred embodiment of the direct/diffuse equalizer 8 is an active filter/equalizer circuit that substantially implements (within 0.3 dB) the inverse of the curve defined by the difference data set forth in ISO 454-1975(E). In practice, such a close tolerance is not required. The difference data in that standard is a table of the amount by which the sound pressure level in a free field exceeds that in a diffuse field for equal loudness. The data is as follows:

Frequency, Hz	Difference, dB
50	0
63	0
80	0
100	0

125	0
160	0
200	0.3
250	0.6
315	0.9
400	1.2
500	1.6
630	2.3
800	2.8
1,000	3.0
1,250	2.0
1,600	0
2,000	− 1.4
2,500	− 2.0
3,150	− 1.9
4,000	− 1.0
5,000	0.5
6,300	3.0
8,000	4.0
10,000	4.3

There is a suggestion in the above-cited article by Theile that ISO 454 does not properly take into account the SLD effect, discussed above. Accordingly, the compensation provided by the standard may be somewhat in error. It is intended that the either ISO 454 or a corrected version thereof should provide the basis for the practical implementation of the equalizer 8.

Figure 7 shows a schematic diagram of a practical embodiment of the direct/diffuse equalizer 8 that implements the inverse of the curve defined by ISO 454-1975(E). It will be noted that the standard provides data up to 10 kHz. This is more than adequate because the frequency response of the surround channel in the standard matrix surround sound system is limited to about 7 kHz. Equalizer 8 employs four sections having a total of five operational amplifiers. Except for the second section, which is a simple RC single pole low pass filter (25 kHz) and buffer (op amp 40), the sections are basically the same circuit topology identified above as known for use as an allpass filter. The first section, including op amp 38, functions as a dip equalizer with a -5.6 dB gain at 1 kHz. The third section, including op amps 42 and 44, uses op amp 42 to provide a phase inversion, causing the section to function as a boost equalizer having a gain of 9 dB at 2.5 kHz. The last section is a further dip equalizer having a -6 dB gain at 8 kHz. The preferred circuit values are as follows:

component	value
48	6K98
50	6K19
52	22N
54	22N
56	6K98
58	6K81

86	7K5

The equalizer circuit of Figure 7 is one practical embodiment of the equalizer means 8 of Figures 1 and 2. Many other filter/equalizer circuit configurations are possible within the teachings of the invention.

In a modification of the embodiments of Figures 1 and 2, the monophonic surround-sound channel advantageously may be split, by appropriate de-correlating means, into two channels which, when applied to first and second surround loudspeakers or groups of loudspeakers, provide two surround channel sound fields having low-interaural cross-correlation with respect to each other at listening positions within the listening room. Preferably, each of the two de-correlated surround channel sound fields is generated by a single loudspeaker. The use of more than a single loudspeaker to generate each field may make it more difficult to match the timbre of the diffuse surround channel sound field to that of the direct left, center, and right channel sound fields. This may be a result of a comb filter effect produced when more than two loudspeakers are used to generate each of the de-correlated surround channel sound fields.

It has previously been established that human perception favors dissimilar sound present at the two ears insofar as the reverberant energy in a listening room is concerned. In order to provide such a dissimilarity when using matrix audio surround-sound technology, added circuitry is needed beyond simple encoding and decoding, since only a monaural surround track is encoded. In principal this circuitry may employ various known techniques for synthesizing stereo from a monaural source, such as comb filtering. However, many of these techniques produce undesirable audible side effects. For example, comb filters suffer from audible "phasiness," which can readily be distinguished by careful listeners.

Preferably, the decorrelation circuitry used in the practical embodiment of this aspect of the invention employs small amounts of frequency or pitch shifting, which is known to be relatively unobtrusive to critical listeners. Pitch shifting, for example, is currently used, besides as an effect, to allow the increase of gain before feedback in public address systems, where it is not easily noticed, the amount of such shifts being small, in the order of a few Hertz. A 5 Hz shift is employed in a modulation-demodulation circuit for this purpose described in "A Frequency Shifter for Improving Acoustic Feedback Stability," by A.J. Prestigiacomo and D.J. Ma-

10

cLean, reprinted in <u>Sound Reinforcement, An Anthology</u>, Audio Engineering Society, 1978, pp. B-6 - B-9.

Frequency or pitch shifting may be accomplished by any of the well-known techniques for doing so. In addition to the method described in the Prestigiacomo and MacLean article, as noted in the <u>Handbook for Sound Engineers, the New Audio Cyclopedia</u>, Howard W. Sams & Co. First Edition, 1987, page 626, delay can form the basis for frequency shift: the signal is applied to the memory of the delay at one rate (the original frequency) and read out at a different rate (the shifted frequency).

The surround channel signal is applied to two paths. At least one path is processed by a pitch shifter. Preferably, the frequency or pitch shift is fixed and is small, sufficient to psychoacoustically de-correlate the sound fields without audibly degrading the sound: in the order of a few Hertz. Although more complex arrangements are possible, they may not be necessary. For example, pitch shifting could be provided in both paths and the pitch could be shifted in a complementary fashion, with one polarity of shift driving the surround channel signal in one path up in frequency, and the other driving the signal in the other path downward in frequency. Other possibilities include varying the pitch shift by varying the clocking of a delay line. The shift could be varied in accordance with the envelope of the surround channel audio signal (e.g., under control of a circuit following the surround channel audio signal having a syllabic time constant--such circuits are well known for use with audio compressors and expanders).

Although either analog or digital delay processing may be employed, the lower cost of digital delay lines suggests digital processing, particularly the use of adaptive delta modulation (ADM) for which relatively inexpensive decoders are available. Conventional pulse code modulation (PCM) also may be used. Although waveform discontinuities ("splices") occur at the signal block sample junctions as the output signal from the delay line is reconstructed whether ADM or PCM is used, such splices tend to be inaudible in the case of ADM because the errors are single bit errors. In the case of PCM, special signal processing is likely required to reduce the audibility of the splices. According to the above cited <u>Handbook for Sound Engineers</u>, several signal-processing techniques have successfully reduced the audibility of such "splices."

Referring to Figure 8, the surround output from matrix decoder 4 (optionally, via direct/diffuse equalizer 8) of Figures 1 or 2 provides the input to the decorrelator which is applied to an anti-aliasing low-pass filter 102 in the signal processing path and to an envelope generator 122 in the control signal path. The filtered input signal is then applied to an analog-to-digital converter (preferably, ADM) 104, the digital output of which is applied to two paths that generate, respectively, the left surround and right surround outputs. The assignment of the "left" and "right" paths is purely arbitrary and the designations may be reversed. The paths are the same and include a clocked delay line 106 (114), a digital-to-analog converter 108 (116) and an anti-imaging low-pass filter 110 (118).

The control signal for controlling the pitch shift by means of altering the clocking of the delay lines 106 and 114 is fixed or variable, according to the position of switch 124, which selects the input to a very low frequency voltage controlled oscillator (VCO) 128 either from the envelope generator 122, which follows the syllabic rate of the surround channel audio signal, or from a fixed source, shown as a variable resistor 126. VCO 128 operates at a very low frequency, less than 5 Hz. The output of the low frequency VCO 128 is applied directly to a high frequency VCO 130 which clocks delay line 106 in the left surround path and is also inverted by inverter 132 for application to a second high frequency VCO 134 which clocks delay line 114 in the right surround path. When there is no output from the low frequency VCO 128, the two high frequency VCOs are set to the same frequency (in the megahertz range, the exact frequency depending on the clock rate required for the delay lines, which in turn depends on the digital sampling rate selected). The low frequency oscillator 128 modulates the high frequency oscillators, producing complementary pitch shifts.

Alternatively, the decorrelator of Figure 8 may be simplified so that the surround output from the matrix decoder is applied without processing in a first path to either the left surround loudspeaker(s) 112 or right surround loudspeaker(s) 120. The other path is applied to the other of the loudspeaker(s) via frequency or pitch shift processing, preferably fixed, including anti-aliasing low-pass filter 102, analog-to-digital converter 104, delay 106, digital-to-analog converter 108, anti-imaging low-pass filter 110. Delay 106 is controlled as shown in Figure 8, preferably with switch 124 selecting the fixed input from potentiometer 126. The amount of frequency shifting required in this variation in which the pitch is shifted only in one channel is about twice that provided to each of the paths in the embodiment of Figure 8.

The output of the paths is applied (through suitable amplification), respectively, to one (preferably) or a group of left surround loudspeakers 112 and to one (preferably) or a group of right surround loudspeakers 120. The loudspeakers should be arranged so that they generate first and second sound fields generally to the left (side and/or rear) and right (side and/or rear) of listening positions within the listening room. The aforementioned techniques regarding the generation of a predominantly diffuse sound field are preferably applied to the decorrelated surround channel.

Claims

1. A surround-sound system for reproducing a motion picture soundtrack having pre-recorded multiple sound channels, including left, right, and surround-sound channels, in a relatively small room, such as in a home, wherein said motion picture soundtrack is equalized for playback in a room whose room-loudspeaker system is aligned to the standard motion picture theater X curve, comprising

loudspeaker means (10, 14) for generating, when located in its or their operating positions with respect to the small room, in response to first and second input signals, first and second sound fields at listening positions within the small room,

means for coupling said left and right sound channels, as said first and second input signals, to said loudspeaker means,

additional loudspeaker means (16) for generating, when located in its or their operating positions with respect to the small room, in response to a third input signal, a third sound field at listening positions within the small room, and

means for coupling said surround-sound channel, as said third input signal, to said additional loudspeaker means,

characterized in that

said means for coupling said left and right sound channels to said loudspeaker means includes means (6) for re-equalizing said left and right sound channels to compensate for said X curve equalization, and said means for re-equalizing comprises a circuit having a transfer characteristic of a low-pass filter with a shelving response such that its characteristic response is flat within about ±1 dB up to a frequency between 4 and 5 kHz, rolls off between this frequency and about 10 kHz, and begins to flatten out above about 10 kHz.

2. The system of claim 1 *further characterized in that* said characteristic response, subject to a tolerance of about ±1 dB up to about 10 kHz and about ±2 dB from about 10 kHz to 20 kHz, is:

Hz	dB
20	0
100	0
500	0
1K	0
2K	-0.2
3K15	-0.4
4K	-0.7
5K	-1.1
6K3	-1.8
8K	-2.8
10K	-4.2
12K5	-5.2
16K	-5.4
20K	-5.7.

3. The system of claims 1, or 2 *further characterized in that* said additional loudspeaker means includes one or more dipole type loudspeakers.

4. The system of claims 1, or 2 *further characterized in that* the direct sound field component is predominant over the diffuse sound field component in each of said first and second sound fields and the diffuse sound field component is predominant over the direct sound field component in said third sound field.

5. The system of claim 4 *further characterized in that* said additional loudspeaker means includes one or more dipole type loudspeakers each oriented with one of their respective nulls generally toward listening positions within the small room.

6. The system of claims 1, 2, 3, 4, or 5 *further characterized in that* said means for coupling said surround channel to said additional loudspeaker means includes means (8) for equalizing the surround channel to compensate for the listener perceived difference in timbre between the sound field of the surround sound channel and the sound fields of the other sound channels.

7. The system of claims 1, 2, 3, 4, 5, or 6 *further characterized in that* said surround-sound system is also for reproducing a center sound channel, said loudspeaker means (10, 12, 14, 16) also generating, when located in its or their operating positions with respect to the small room, in response to a fourth input signal a fourth sound field at listening positions within the small room, and means for coupling said center sound channel, as said fourth input signal, to said loudspeaker means, said means for coupling said center sound channel to said loudspeaker means including means (6) for re-equalizing said center sound channel to compensate for said X curve equalization.

8. The system of claims 1, 2, 3, 4, 5, or 6 *further characterized in that* said additional loudspeaker means (16) includes first and second additional loudspeakers or groups of loudspeakers (112, 120) and wherein said means for coupling said surround-sound channel further includes means for deriving two sound channels from said surround-sound channel, which, when reproduced by said first and second additional loudspeakers or groups of loudspeakers located in their operating positions with respect to the small room, generate first and second surround-sound fields having low-interaural cross-correlation with respect to each other at listening positions within the small room and said means for coupling said surround-sound channel couples said two sound channels to said first and second surround-sound channel loudspeakers or groups of loudspeakers.

9. The system of claim 8 *further characterized in that* said means for deriving two sound channels from said surround-sound channel includes means for shifting the pitch of said two sound channels with respect to each other.

10. The system of claim 6 *further characterized in that* said means for equalizing the surround channel includes means for reducing the comb filter effect when the surround channel is reproduced in a listening room.

11. A method for reproducing a motion picture soundtrack having pre-recorded multiple sound channels, including left, right, and surround-sound channels, in a relatively small room, such as in a home, wherein said motion picture soundtrack is equalized for playback in a room whose room-loudspeaker system is aligned to the standard motion picture theater X curve, comprising
    generating, in response to applied sound channels, first and second sound fields at listening positions within the small room, and
    generating, in response to said surround-sound channel, a third sound field at listening positions within the small room,
    characterized in that the left and right sound channels are re-equalized (6) to compensate for said X curve equalization and said first and second sound fields are generated in response to the re-equalized left and right sound channels, and the re-equalizing has a transfer characteristic of a low-pass filter with a shelving response such that its characteristic response is flat within about ± 1 dB up to a frequency between 4 and 5 kHz., rolls off between this frequency and about 10 kHz, and begins to flatten out above about 10 kHz.

12. The method of claim 11 *further characterized in that* said characteristic response, subject to a tolerance of about ±1 dB up to about 10 kHz and about ±2 dB from about 10 kHz to 20 kHz, is:

Hz	dB
20	0
100	0
500	0
1K	0
2K	-0.2
3K15	-0.4
4K	-0.7
5K	-1.1
6K3	-1.8
8K	-2.8
10K	-4.2
12K5	-5.2
16K	-5.4
20K	-5.7.

13. The method of claims 11 or 12 *further characterized in that* the direct sound field component is predominant over the diffuse sound field component in each of said first and second sound fields and the diffuse sound field component is predominant over the direct sound field component in said third sound field.

14. The method of claims 11, 12, or 13 *further characterized by* equalizing the surround channel to compensate for the listener perceived difference in timbre between the sound field of the surround sound channel and the sound fields of the other sound channels.

15. The method of claims 11, 12 or 13 *further characterized in that* in response to said surround-sound channel, third and fourth sound fields having low-interaural cross-correlation with respect to each other are generated at listening positions within the small room.

Patentansprüche

1. Räumliches Schallwiedergabesystem für eine Filmtonspur mit bespielten, mehrfachen Tonkanälen, einschließlich linker, rechter und von Raumklangkanälen in einem verhältnismäßig kleinen Raum, beispielsweise in einem Privathaus, worin die Tonfilmspur zur Wiedergabe in einem Raum ausgeglichen ist, dessen Raumlautsprechersystem auf auf die genormte X-Kurve für Kinos abgeglichen ist, mit
     Lautsprechereinrichtungen (10, 14) die, wenn sie sich in ihrer oder ihren Betriebsstellungen in bezug auf den kleinen Raum befindet oder befinden in Abhängigkeit von ersten und zweiten Eingangssignalen erste und zweite Schallfelder an Hörpositionen innerhalb des kleinen Raums erzeugen,
     Einrichtungen zum Koppeln der linken und rechten Tonkanäle als erste und zweite Eingangssignale an die Lautsprechereinrichtungen, zusätzlichen Lautsprechereinrichtungen (16) die, wenn sie sich in ihrer oder ihren Betriebsstellungen in bezug auf den kleinen Raum befinden, in Abhängigkeit von einem dritten Eingangssignal ein drittes Schallfeld an Hörpositionen innerhalb des kleinen Raums erzeugen, und Einrichtungen zum Koppeln des Raumklangkanals als das dritte Eingangssignal an die zusätzlichen Lautsprechereinrichtungen,
     dadurch gekennzeichnet, daß die Einrichtung zum Koppeln des linken und rechten Tonkanals mit den Lautsprechereinrichtungen Einrichtungen (6) zur Wiederentzerrung der linken und rechten Tonkanäle zwecks Kompensation des genannten X-Kurvenausgleichs enthält, und daß die Einrichtung zur Wiederentzerrung einen Schaltkreis aufweist, der eine Übertragungscharakteristik eines Tiefpaßfilters mit einem Steilküstenverlauf hat, so daß sein Kurvenverlauf innerhalb etwa ± 1 dB bis zu einer Frequenz zwischen 4 und 5 kHz flach ist, zwischen dieser Frequenz und etwa 10 kHz abfällt, und oberhalb 10 kHz sich

abzuflachen beginnt.

2. System nach Anspruch 1, ferner dadurch gekennzeichnet, daß der Kurvenverlauf mit einer Toleranz von etwa ± 1 dB bis zu etwa 10 kHz und ca. ±2 dB von etwa 10 kHz bis 20 kHz, ist:

Hz	dB
20	0
100	0
500	0
1K	0
2K	-0,2
3K15	-0,4
4K	-0,7
5K	-1,1
6K3	-1,8
8K	-2,8
10K	-4,2
12K5	-5,2
16K	-5,4
20K	-5,7

3. System nach Anspruch 1 oder 2, ferner dadurch gekennzeichnet, daß die zusätzliche Lautsprechereinrichtung einen oder mehr Lautsprecher des Dipoltyps einschließt.

4. System nach Anspruch 1 oder 2, ferner dadurch gekennzeichnet, daß die Komponente des direkten Schallfeldes in jedem der ersten und zweiten Schallfelder gegenüber der Komponente des diffusen Schallfeldes prädominant ist, und daß die Komponente des diffusen Schallfeldes in dem dritten Schallfeld gegenüber der Komponente des direkten Schallfeldes prädominant ist.

5. System nach Anspruch 4, ferner dadurch gekennzeichnet, daß die zusätzliche Lautsprechereinrichtung einen oder mehrere Lautsprecher des Dipoltyps einschließt, die jeweils mit einer ihrer entsprechenden Nullen insgesamt in Richtung auf Hörpositionen innerhalb des kleinen Raums ausgerichtet sind.

6. System nach Anspruch 1, 2, 3, 4 oder 5, ferner dadurch gekennzeichnet, daß die Einrichtung zum Koppeln des Raumklangkanals an die zusätzliche Lautsprechereinrichtung Einrichtungen (8) zum Entzerren des Raumklangkanals zwecks Kompensation für die vom Zuhörer wahrgenommene Differenz in der Klangfarbe zwischen dem Schallfeld des Raumklangkanals und den Schallfeldern der anderen Tonkanäle enthält.

7. System nach Anspruch 1, 2, 3, 4, 5 oder 6, ferner dadurch gekennzeichnet, daß das räumliche Schallwiedergabesystem auch für die Wiedergabe eines Mitteltonkanals ist, daß die Lautsprechereinrichtungen (10, 12, 14, 16), wenn sie sich in ihrer oder ihren Betriebsstellungen in bezug auf den kleinen Raum befinden, in Abhängigkeit von einem vierten Eingangssignal auch ein viertes Schallfeld an Hörpositionen innerhalb des kleinen Raums erzeugen, und Einrichtungen zum Koppeln des Mitteltonkanals als das vierte Eingangssignal an die Lautsprechereinrichtungen, wobei die Einrichtungen zum Koppeln des Mitteltonkanals mit den Lautsprechereinrichtungen Einrichtungen (6) zur Wiederentzerrung des Mitteltonkanals zwecks Kompensation für den X-Kurvenausgleich enthalten.

8. System nach Anspruch 1, 2, 3, 4, 5 oder 6, ferner dadurch gekennzeichnet, daß die zusätzliche Lautsprechereinrichtung (16) erste und zweite zusätzliche Lautsprecher oder Gruppen von Lautsprechern (112, 120) einschließt, und worin die Einrichtung zum Koppeln des Raumklangkanals ferner Einrichtungen zum Ableiten von Zweitonkanälen vom Raumklangkanal einschließt, die, wenn sie von den ersten und zweiten zusätzlichen Lautsprechern oder Gruppen von Lautsprechern wiedergegeben werden, welche sich in ihren Betriebsstellungen in bezug auf den kleinen Raum befinden, erste und zweite Raumklangfelder er-

15

zeugen, die im Verhältnis zueinander eine schwache interaurale Kreuz-Korrelation an Hörpositionen innerhalb des kleinen Raums haben, und die Einrichtung zum Koppeln des Raumklangkanals die beiden Tonkanäle mit den ersten und zweiten Raumklangkanallautsprechern oder Gruppen von Lautsprechern koppelt.

9. System nach Anspruch 8, ferner dadurch gekennzeichnet, daß die Einrichtung zum Ableiten von Zweitonkanälen von dem Raumklangkanal Einrichtungen zum Verschieben der Tonhöhe der beiden Tonkanäle im Verhältnis zueinander einschließt.

10. System nach Anspruch 6, ferner dadurch gekennzeichnet, daß die Einrichtung zum Entzerren des Raumklangkanals Einrichtungen zum Mindern der Kammfilterwirkung einschließt, wenn der Raumklangkanal in einem Zuhörraum wiedergegeben wird.

11. Verfahren zur Wiedergabe einer Filmtonspur mit bespielten, mehrfachen Tonkanälen, einschließlich linker, rechter und von Raumklangkanälen, in einem verhältnismäßig kleinen Raum, beispielsweise in einem Privathaus, worin die Filmtonspur für die Wiedergabe in einem Raum ausgeglichen ist, dessen Raumlautsprechersystem auf die genormte X-Kurve für Kinos abgeglichen ist, mit
Erzeugung erster und zweiter Schallfelder an Hörpositionen innerhalb des kleinen Raums in Abhängigkeit von angelegten Tonkanälen, und
Erzeugung eines dritten Schallfeldes an Hörpositionen innerhalb des kleinen Raums in Abhängigkeit von dem Raumklangkanal,
dadurch gekennzeichnet, daß die linken und rechten Tonkanäle wiederentzerrt (6) werden, um den X-Kurvenausgleich zu kompensieren, und daß die ersten und zweiten Schallfelder in Abhängigkeit von den wiederentzerrten linken und rechten Tonkanälen erzeugt werden, und daß die Wiederentzerrung eine Übertragungscharakteristik eines Tiefpaßfilters mit einem Steilküstenverlauf hat, so daß ihr Kurvenverlauf innerhalb ca. ± 1 dB bis zu einer Frequenz zwischen 4 und 5 kHz flach ist, zwischen dieser Frequenz und etwa 10 kHz abfällt und sich oberhalb etwa 10 kHz abzuflachen beginnt.

12. Verfahren nach Anspruch 11, ferner dadurch gekennzeichnet, daß der Kurvenverlauf vorbehaltlich einer Toleranz von ca. ± 1 dB bis zu etwa 10 kHz und ca. ± 2 dB von etwa 10 kHz bis 20 kHz folgender ist:

Hz	dB
20	0
100	0
500	0
1K	0
2K	-0,2
3K15	-0,4
4K	-0,7
5K	-1,1
6K3	-1,8
8K	-2,8
10K	-4,2
12K5	-5,2
16K	-5,4
20K	-5,7

13. Verfahren nach Anspruch 11 oder 12, ferner dadurch gekennzeichnet, daß die Komponente des direkten Schallfeldes in jedem der ersten und zweiten Schallfelder gegenüber der Komponente des diffusen Schallfeldes prädominant ist, und daß die Komponente des diffusen Schallfeldes in dem dritten Schallfeld gegenüber der Komponente des direkten Schallfeldes prädominant ist.

14. Verfahren nach Anspruch 11, 12 oder 13, ferner dadurch gekennzeichnet, daß der Raumklangkanal ent-

zerrt wird, um einen Ausgleich zu schaffen für den vom Zuhörer wahrgenommenen Unterschied in der Klangfarbe zwischen dem Schallfeld des Raumklangkanals und den Schallfeldern der anderen Tonkanäle.

15. Verfahren nach Anspruch 11, 12 oder 13, ferner dadurch gekennzeichnet, daß in Abhängigkeit von dem Raumklangkanal dritte und vierteerfahren nach Anspruch 11, 12 oder 13, ferner dadurch gekennzeichnet, daß in Abhängigkeit von dem Raumklangkanal dritte und vierte Schallfelder mit schwacher interauraler Kreuzkorrelation im Verhältnis zueinander an Hörpositionen innerhalb des kleinen Raums erzeugt werden.

Revendications

1. Système sonore à effet spatial pour reproduire une piste sonore d'images animées ayant de multiples canaux sonores pré-enregistrés, comprenant des canaux gauche, droit et sonore à effet spatial, dans un local relativement petit, comme dans une maison, dans lequel ladite piste sonore d'images animées est égalisée pour la lecture dans un local dont le système de haut-parleurs pour local est aligné sur la courbe X standard pour salles de cinéma, comprenant

    un (des) élément(s) de haut-parleur (10, 14) pour générer, quand il est situé/ils sont situés dans ses ou leurs positions de fonctionnement par rapport au petit local, en réponse aux premier et deuxième signaux d'entrée, les premier et deuxième champs sonores au niveau des positions d'audition à l'intérieur du petit local,

    un élément pour coupler lesdits canaux sonores gauche et droit, en tant que premier et deuxième signaux d'entrée, audit élément de haut-parleur.

    un (des) élément(s) de haut-parleur supplémentaire(s) (16) pour générer, quand il est situé/ils sont situés dans ses ou leurs positions de fonctionnement par rapport au petit local, en réponse à un troisième signal d'entrée, un troisième champ sonore au niveau des positions d'audition à l'intérieur du petit local,

    un élément pour coupler ledit canal sonore à effet spatial, en tant que troisième signal d'entrée, audit élément de haut-parleur supplémentaire,

    caractérisé en ce que

    ledit élément pour coupler lesdits canaux sonores gauche et droit audit élément de haut-parleur comprend un élément (6) pour ré-égaliser lesdits canaux sonores gauche et droit afin de compenser ladite égalisation par courbe X, et ledit élément de ré-égalisation comprend un circuit ayant une caractéristique de transfert d'un filtre passe-bas avec une réponse étagée telle que sa réponse caractéristique est plate en deçà d'environ ±1 dB jusqu'à une fréquence comprise entre 4 et 5 kHz, présente une atténuation croissante entre cette fréquence et environ 10 kHz et commence à s'aplatir au-dessus de 10 kHz environ.

2. Système suivant la revendication 1 également caractérisé en ce que ladite réponse caractéristique soumise à une tolérance d'environ ±1 dB jusqu'à environ 10 kHz et environ ±2 dB de 10 kHz environ à 20 kHz, est :

Hz	dB
20	0
100	0
500	0
1K	0
2K	−0,2
3K15	−0,4
4K	−0,7
5K	−1,1
6K3	−1,8
8K	−2,8
10K	−4,2
12K5	−5,2
16K	−5,4
20K	−5,7.

3. Système suivant les revendications 1, ou 2, également caractérisé en ce que l'élément de haut-parleur supplémentaire comprend un haut-parleur de type dipolaire ou davantage.

4. Système suivant les revendications 1, ou 2, également caractérisé en ce que la composante de champ sonore direct l'emporte sur la composante de champ sonore diffus dans chacun desdits premier et deuxième champs sonores et en ce que la composante de champ sonore diffus l'emporte sur a composante de champ sonore directe dans ledit troisième champ sonore.

5. Système suivant la revendication 4, également caractérisé en ce que ledit élément de haut-parleur supplémentaire comprend un haut-parleur de type dipolaire ou davantage, chacun orienté avec un de leurs zéros respectifs dirigés généralement vers les positions d'audition à l'intérieur du petit local.

6. Système suivant les revendications 1, 2, 3, 4 ou 5, caractérisé également en ce que ledit élément de couplage dudit canal à effet spatial audit élément de haut-parleur supplémentaire comprend un élément (8) pour l'égalisation du canal à effet spatial afin de compenser la différence, perçue par l'auditeur, de timbre entre le champ sonore du canal sonore à effet spatial et les champs sonores des autres canaux sonores.

7. Système suivant les revendications 1, 2, 3, 4, 5 ou 6, caractérisé également en ce que ledit système sonore à effet spatial est également destiné à reproduire un canal sonore central, le(s)dit(s) élément(s) de haut-parleur (10, 12, 14, 16) générant également, quand il est situé/ils sont situés dans ses ou leurs positions de fonctionnement par rapport au petit local, en réponse à un quatrième signal d'entrée, un quatrième champ sonore au niveau des positions d'audition à l'intérieur du petit local, et un élément de couplage dudit canal sonore central, en tant que quatrième signal d'entrée, audit élément de haut-parleur, ledit élément de couplage dudit canal sonore central audit élément de haut-parleur comprenant un élément (6) de ré-égalisation dudit canal sonore central afin de compenser ladite égalisation de courbe X.

8. Système suivant les revendications 1, 2, 3, 4, 5 ou 6, caractérisé également en ce que ledit élément de haut-parleur supplémentaire (16) comprend les premier et second haut-parleurs supplémentaires ou groupes de haut-parleurs supplémentaires (112, 120) et dans lequel ledit élément de couplage dudit canal sonore à effet spatial comprend également des éléments pour dériver deux canaux sonores à partir dudit canal sonore à effet spatial qui, quand ils sont reproduits par lesdits premier et second haut-parleurs supplémentaires ou groupes de haut-parleurs supplémentaires situés dans leurs positions de fonctionnement par rapport au petit local, génèrent des premier et deuxième champs sonores à effet spatial ayant une

intercorrélation interaudio faible l'un par rapport à l'autre au niveau des positions d'audition à l'intérieur du petit local et ledit élément de couplage dudit canal sonore à effet spatial couple lesdits deux canaux sonores auxdits premier et deuxième haut-parleurs ou groupes de haut-parleurs de canal sonore à effet spatial.

9. Système suivant la revendication 8, caractérisé également en ce que ledit élément chargé de dériver deux canaux sonores à partir dudit canal sonore à effet spatial comprend un élément chargé de déplacer la hauteur de son desdits deux canaux l'un par rapport à l'autre.

10. Système suivant la revendication 6, caractérisé également en ce que ledit élément d'égalisation du canal à effet spatial comprend un élément chargé de réduire l'effet de filtre en peigne quand le canal à effet spatial est reproduit dans un local d'audition.

11. Méthode pour reproduire une piste sonore d'images animées ayant de multiples canaux sonores pré-en-registrés, comprenant les canaux gauche, droit et sonore à effet spatial, dans un local relativement petit, comme dans une maison, dans laquelle méthode ladite piste sonore d'images animées est égalisée pour une lecture dans un local dont le système de haut-parleur pour local est aligné sur la courbe X de salle de cinéma, comprenant

la génération, en réponse à des canaux sonores appliqués, de premier et deuxième champs sonores au niveau de positions d'audition à l'intérieur du petit local, et

la génération, en réponse audit canal sonore à effet spatial, d'un troisième champ sonore au niveau de positions d'audition à l'intérieur du petit local,

caractérisée en ce que les canaux sonores gauche et droit sont ré-égalisés (6) pour compenser ladite égalisation par courbe X et en ce que lesdits premier et deuxième champs sonores sont générés en réponse aux canaux sonores gauche et droit ré-égalisés et en ce que la ré-égalisation a une caractéristique de transfert d'un filtre passe-bas avec une réponse étagée telle que sa réponse caractéristique est plate se situant à ± 1dB environ jusqu'à une fréquence comprise entre 4 et 5 kHz, présente une atténuation croissante entre cette fréquence et environ 10 kHz et commence à s'aplatir au-dessus de 10 kHz environ.

12. Méthode suivant la revendication 11, également caractérisée en ce que la réponse caractéristique, soumise à une tolérance d'environ ±1 dB jusqu'à 10 kHz environ et d'environ ±2 dB d'environ 10 kHz à 20 kHz, est :

Hz	dB
20	0
100	0
500	0
1K	0
2K	−0,2
3K15	−0,4
4K	−0,7
5K	−1,1
6K3	−1,8
8K	−2,8
10K	−4,2
12K5	−5,2
16K	−5,4
20K	−5,7 .

13. Méthode suivant les revendications 11 ou 12, caractérisée également en ce que la composante de champ sonore direct l'emporte sur la composante de champ sonore diffus dans chacun desdits premier et deuxiè- me champs sonores et en ce que la composante de champ sonore diffus l'emporte sur la composante de champ sonore direct dans ledit troisième champ sonore.

14. Méthode suivant les revendications 11, 12 ou 13, caractérisée également par l'égalisation du canal sonore à effet spatial pour compenser la différence, perçue par l'auditeur, de timbre entre le champ sonore du canal sonore à effet spatial et les champs sonores des autres canaux sonores.

15. Méthode suivant les revendications 11, 12 ou 13, caractérisée également en ce que, en réponse audit canal sonore à effet spatial, des troisième et quatrième champs sonores ayant une intercorrélation inte- raudio faible l'un par rapport à l'autre sont générés au niveau de positions d'audition à l'intérieur du petit local.
