(54) Title: SYSTEM AND METHOD FOR A TURBINE COMBUSTOR

FIG. 5

(57) Abstract: A system includes a turbine combustor, which includes a first wall disposed about a combustion chamber, a second wall disposed about the first wall, and a third wall disposed about the second wall. The third wall is configured to combine an exhaust gas with an oxidant and the combustion chamber is configured to combust a mixture of a fuel, the oxidant, and the exhaust gas.

SYSTEM AND METHOD FOR A TURBINE COMBUSTOR

CROSS REFERENCE TO RELATED APPLICATIONS

BACKGROUND OF THE INVENTION

[0002] The subject matter disclosed herein relates to gas turbine engines, and more specifically, to systems and methods for turbine combustors of gas turbine engines.

[0003] Gas turbine engines are used in a wide variety of applications, such as power generation, aircraft, and various machinery. Gas turbine engines generally combust a fuel with an oxidant (e.g., air) in a combustor section to generate hot
combustion products, which then drive one or more turbine stages of a turbine section. In turn, the turbine section drives one or more compressor stages of a compressor section, thereby compressing oxidant for intake into the combustor section along with the fuel. Again, the fuel and oxidant mix in the combustor section, and then combust to produce the hot combustion products. Gas turbine engines generally premix the fuel and oxidant along one or more flow paths upstream from a combustion chamber of the combustor section. Unfortunately, certain components of the combustor section are exposed to high temperatures, which may reduce the life of the components. Furthermore, gas turbine engines typically consume a vast amount of air as the oxidant, and output a considerable amount of exhaust gas into the atmosphere. In other words, the exhaust gas is typically wasted as a byproduct of the gas turbine operation.

BRIEF DESCRIPTION OF THE INVENTION

[0004] Certain embodiments commensurate in scope with the originally claimed invention are summarized below. These embodiments are not intended to limit the scope of the claimed invention, but rather these embodiments are intended only to provide a brief summary of possible forms of the invention. Indeed, the invention may encompass a variety of forms that may be similar to or different from the embodiments set forth below.

[0005] In a first embodiment, a system includes a turbine combustor, which includes a first wall disposed about a combustion chamber, a second wall disposed about the first wall, and a third wall disposed about the second wall. The third wall is configured to combine an exhaust gas with an oxidant and the combustion chamber is configured to combust a mixture of a fuel, the oxidant, and the exhaust gas.

[0006] In a second embodiment, a system includes a triple-wall turbine combustor, which includes a first wall disposed about a combustion chamber, a second wall disposed about the first wall, and a third wall disposed about the second wall. The at least one of the first, second, and third walls is configured to pass an exhaust gas and
the combustion chamber is configured to combust a mixture of a fuel, an oxidant, and the exhaust gas.

[0007] In a third embodiment, a method includes flowing an exhaust gas and an oxidant along a flow path of a multi-wall turbine combustor between a first wall surrounding a combustion chamber, a second wall surrounding the first wall, and a third wall surrounding the second wall. The method also includes combusting a mixture of a fuel, the oxidant, and the exhaust gas within the combustion chamber.

BRIEF DESCRIPTION OF THE DRAWINGS

[0008] These and other features, aspects, and advantages of the present invention will become better understood when the following detailed description is read with reference to the accompanying drawings in which like characters represent like parts throughout the drawings, wherein:

[0009] FIG. 1 is a diagram of an embodiment of a system having a turbine-based service system coupled to a hydrocarbon production system;

[0010] FIG. 2 is a diagram of an embodiment of the system of FIG. 1, further illustrating a control system and a combined cycle system;

[0011] FIG. 3 is a diagram of an embodiment of the system of FIGS. 1 and 2, further illustrating details of a gas turbine engine, exhaust gas supply system, and exhaust gas processing system;

[0012] FIG. 4 is a flow chart of an embodiment of a process for operating the system of FIGS. 1-3;

[0013] FIG. 5 is a cutaway side view of an embodiment of a turbine combustor;

[0014] FIG. 6 is a cutaway side view of an embodiment of a turbine combustor with a bypass tube;

[0015] FIG. 7 is a cutaway side view of an embodiment of a turbine combustor with a flow path that reverses directions;
FIG. 8 is a cutaway side view of an embodiment of a turbine combustor with an oxidant conduit extending through a casing of the turbine combustor; and

FIG. 9 is a cross-sectional view of a portion of an embodiment illustrating a plurality of turbulators.

DETAILED DESCRIPTION OF THE INVENTION

One or more specific embodiments of the present invention will be described below. In an effort to provide a concise description of these embodiments, all features of an actual implementation may not be described in the specification. It should be appreciated that in the development of any such actual implementation, as in any engineering or design project, numerous implementation-specific decisions must be made to achieve the developers' specific goals, such as compliance with system-related and business-related constraints, which may vary from one implementation to another. Moreover, it should be appreciated that such a development effort might be complex and time consuming, but would nevertheless be a routine undertaking of design, fabrication, and manufacture for those of ordinary skill having the benefit of this disclosure.

When introducing elements of various embodiments of the present invention, the articles "a," "an," "the," and "said" are intended to mean that there are one or more of the elements. The terms "comprising," "including," and "having" are intended to be inclusive and mean that there may be additional elements other than the listed elements.

As discussed in detail below, the disclosed embodiments relate generally to gas turbine systems with exhaust gas recirculation (EGR), and particularly stoichiometric operation of the gas turbine systems using EGR. For example, the gas turbine systems may be configured to recirculate the exhaust gas along an exhaust recirculation path, stoichiometrically combust fuel and oxidant along with at least some of the recirculated exhaust gas, and capture the exhaust gas for use in various target systems. The recirculation of the exhaust gas along with stoichiometric combustion may help to increase the concentration level of carbon dioxide (CO₂) in
the exhaust gas, which can then be post treated to separate and purify the CO₂ and nitrogen (N₂) for use in various target systems. The gas turbine systems also may employ various exhaust gas processing (e.g., heat recovery, catalyst reactions, etc.) along the exhaust recirculation path, thereby increasing the concentration level of CO₂, reducing concentration levels of other emissions (e.g., carbon monoxide, nitrogen oxides, and unburnt hydrocarbons), and increasing energy recovery (e.g., with heat recovery units). Furthermore, the gas turbine engines may be configured to combust the fuel and oxidant with one or more diffusion flames (e.g., using diffusion fuel nozzles), premix flames (e.g., using premix fuel nozzles), or any combination thereof. In certain embodiments, the diffusion flames may help to maintain stability and operation within certain limits for stoichiometric combustion, which in turn helps to increase production of CO₂. For example, a gas turbine system operating with diffusion flames may enable a greater quantity of EGR, as compared to a gas turbine system operating with premix flames. In turn, the increased quantity of EGR helps to increase CO₂ production. Possible target systems include pipelines, storage tanks, carbon sequestration systems, and hydrocarbon production systems, such as enhanced oil recovery (EOR) systems.

[0021] The disclosed embodiments provide systems and methods for turbine combustors of gas turbine systems with EGR. Specifically, the turbine combustor may include a first wall disposed about a combustion chamber, a second wall disposed about the first wall, and a third wall disposed about the second wall. The combustion chamber may combust a mixture of the fuel, oxidant, and exhaust gas. In certain embodiments, the third wall is configured to combine the exhaust gas with the oxidant. In other embodiments, at least one of the first, second, and third walls is configured to pass the exhaust gas. Thus, the third wall may be used to direct the exhaust gas through a desired flow path of the turbine combustor. For example, the third wall may be used to provide a longer flow path for the exhaust gas to combine with the oxidant, thereby improving mixing of the exhaust gas with the oxidant, which may improve the combustion efficiency of the turbine combustor. In addition, the longer flow path associated with the third wall may improve cooling of certain components of the turbine combustor. Specifically, the mixture of the exhaust gas and
the oxidant may be cooler than the combustion gases generated by the turbine combustor. Thus, the third wall may be used to direct the mixture of the exhaust gas and the oxidant along surfaces of the turbine combustor for cooling purposes, which may increase the longevity of the components. In other words, the longevity of certain components of the turbine combustor may be reduced at high temperatures and the third wall may be used to help cool those components. In addition, the third wall may be used to help improve the routing and layout of lines or conduits used to convey the exhaust gas to and from the turbine combustor, thereby improving the overall layout and maintenance accessibility of the gas turbine system.

[0022] FIG. 1 is a diagram of an embodiment of a system 10 having an hydrocarbon production system 12 associated with a turbine-based service system 14. As discussed in further detail below, various embodiments of the turbine-based service system 14 are configured to provide various services, such as electrical power, mechanical power, and fluids (e.g., exhaust gas), to the hydrocarbon production system 12 to facilitate the production or retrieval of oil and/or gas. In the illustrated embodiment, the hydrocarbon production system 12 includes an oil/gas extraction system 16 and an enhanced oil recovery (EOR) system 18, which are coupled to a subterranean reservoir 20 (e.g., an oil, gas, or hydrocarbon reservoir). The oil/gas extraction system 16 includes a variety of surface equipment 22, such as a Christmas tree or production tree 24, coupled to an oil/gas well 26. Furthermore, the well 26 may include one or more tubulars 28 extending through a drilled bore 30 in the earth 32 to the subterranean reservoir 20. The tree 24 includes one or more valves, chokes, isolation sleeves, blowout preventers, and various flow control devices, which regulate pressures and control flows to and from the subterranean reservoir 20. While the tree 24 is generally used to control the flow of the production fluid (e.g., oil or gas) out of the subterranean reservoir 20, the EOR system 18 may increase the production of oil or gas by injecting one or more fluids into the subterranean reservoir 20.

[0023] Accordingly, the EOR system 18 may include a fluid injection system 34, which has one or more tubulars 36 extending through a bore 38 in the earth 32 to the subterranean reservoir 20. For example, the EOR system 18 may route one or more
fluids 40, such as gas, steam, water, chemicals, or any combination thereof, into the fluid injection system 34. For example, as discussed in further detail below, the EOR system 18 may be coupled to the turbine-based service system 14, such that the system 14 routes an exhaust gas 42 (e.g., substantially or entirely free of oxygen) to the EOR system 18 for use as the injection fluid 40. The fluid injection system 34 routes the fluid 40 (e.g., the exhaust gas 42) through the one or more tubulars 36 into the subterranean reservoir 20, as indicated by arrows 44. The injection fluid 40 enters the subterranean reservoir 20 through the tubular 36 at an offset distance 46 away from the tubular 28 of the oil/gas well 26. Accordingly, the injection fluid 40 displaces the oil/gas 48 disposed in the subterranean reservoir 20, and drives the oil/gas 48 up through the one or more tubulars 28 of the hydrocarbon production system 12, as indicated by arrows 50. As discussed in further detail below, the injection fluid 40 may include the exhaust gas 42 originating from the turbine-based service system 14, which is able to generate the exhaust gas 42 on-site as needed by the hydrocarbon production system 12. In other words, the turbine-based system 14 may simultaneously generate one or more services (e.g., electrical power, mechanical power, steam, water (e.g., desalinated water), and exhaust gas (e.g., substantially free of oxygen)) for use by the hydrocarbon production system 12, thereby reducing or eliminating the reliance on external sources of such services.

[0024] In the illustrated embodiment, the turbine-based service system 14 includes a stoichiometric exhaust gas recirculation (SEGR) gas turbine system 52 and an exhaust gas (EG) processing system 54. The gas turbine system 52 may be configured to operate in a stoichiometric combustion mode of operation (e.g., a stoichiometric control mode) and a non-stoichiometric combustion mode of operation (e.g., a non-stoichiometric control mode), such as a fuel-lean control mode or a fuel-rich control mode. In the stoichiometric control mode, the combustion generally occurs in a substantially stoichiometric ratio of a fuel and oxidant, thereby resulting in substantially stoichiometric combustion. In particular, stoichiometric combustion generally involves consuming substantially all of the fuel and oxidant in the combustion reaction, such that the products of combustion are substantially or entirely free of unburnt fuel and oxidant. One measure of stoichiometric combustion is the
equivalence ratio, or phi (φ), which is the ratio of the actual fuel/oxidant ratio relative to the stoichiometric fuel/oxidant ratio. An equivalence ratio of greater than 1.0 results in a fuel-rich combustion of the fuel and oxidant, whereas an equivalence ratio of less than 1.0 results in a fuel-lean combustion of the fuel and oxidant. In contrast, an equivalence ratio of 1.0 results in combustion that is neither fuel-rich nor fuel-lean, thereby substantially consuming all of the fuel and oxidant in the combustion reaction. In context of the disclosed embodiments, the term stoichiometric or substantially stoichiometric may refer to an equivalence ratio of approximately 0.95 to approximately 1.05. However, the disclosed embodiments may also include an equivalence ratio of 1.0 plus or minus 0.01, 0.02, 0.03, 0.04, 0.05, or more. Again, the stoichiometric combustion of fuel and oxidant in the turbine-based service system 14 may result in products of combustion or exhaust gas (e.g., 42) with substantially no unburnt fuel or oxidant remaining. For example, the exhaust gas 42 may have less than 1, 2, 3, 4, or 5 percent by volume of oxidant (e.g., oxygen), unburnt fuel or hydrocarbons (e.g., HCs), nitrogen oxides (e.g., NOx), carbon monoxide (CO), sulfur oxides (e.g., SOx), hydrogen, and other products of incomplete combustion. By further example, the exhaust gas 42 may have less than approximately 10, 20, 30, 40, 50, 60, 70, 80, 90, 100, 200, 300, 400, 500, 1000, 2000, 3000, 4000, or 5000 parts per million by volume (ppmv) of oxidant (e.g., oxygen), unburnt fuel or hydrocarbons (e.g., HCs), nitrogen oxides (e.g., NOx), carbon monoxide (CO), sulfur oxides (e.g., SOx), hydrogen, and other products of incomplete combustion. However, the disclosed embodiments also may produce other ranges of residual fuel, oxidant, and other emissions levels in the exhaust gas 42. As used herein, the terms emissions, emissions levels, and emissions targets may refer to concentration levels of certain products of combustion (e.g., NOx, CO, SOx, \(N_2\), \(H_2\), HCs, etc.), which may be present in recirculated gas streams, vented gas streams (e.g., exhausted into the atmosphere), and gas streams used in various target systems (e.g., the hydrocarbon production system 12).

[0025] Although the SEGR gas turbine system 52 and the EG processing system 54 may include a variety of components in different embodiments, the illustrated EG processing system 54 includes a heat recovery steam generator (HRSG) 56 and an
exhaust gas recirculation (EGR) system 58, which receive and process an exhaust gas originating from the SEGR gas turbine system 52. The HRSG 56 may include one or more heat exchangers, condensers, and various heat recovery equipment, which collectively function to transfer heat from the exhaust gas 60 to a stream of water, thereby generating steam 62. The steam 62 may be used in one or more steam turbines, the EOR system 18, or any other portion of the hydrocarbon production system 12. For example, the HRSG 56 may generate low pressure, medium pressure, and/or high pressure steam 62, which may be selectively applied to low, medium, and high pressure steam turbine stages, or different applications of the EOR system 18. In addition to the steam 62, a treated water 64, such as a desalinated water, may be generated by the HRSG 56, the EGR system 58, and/or another portion of the EG processing system 54 or the SEGR gas turbine system 52. The treated water 64 (e.g., desalinated water) may be particularly useful in areas with water shortages, such as inland or desert regions. The treated water 64 may be generated, at least in part, due to the large volume of air driving combustion of fuel within the SEGR gas turbine system 52. While the on-site generation of steam 62 and water 64 may be beneficial in many applications (including the hydrocarbon production system 12), the on-site generation of exhaust gas 42, 60 may be particularly beneficial for the EOR system 18, due to its low oxygen content, high pressure, and heat derived from the SEGR gas turbine system 52. Accordingly, the HRSG 56, the EGR system 58, and/or another portion of the EG processing system 54 may output or recirculate an exhaust gas 66 into the SEGR gas turbine system 52, while also routing the exhaust gas 42 to the EOR system 18 for use with the hydrocarbon production system 12. Likewise, the exhaust gas 42 may be extracted directly from the SEGR gas turbine system 52 (i.e., without passing through the EG processing system 54) for use in the EOR system 18 of the hydrocarbon production system 12.

The exhaust gas recirculation is handled by the EGR system 58 of the EG processing system 54. For example, the EGR system 58 includes one or more conduits, valves, blowers, exhaust gas treatment systems (e.g., filters, particulate removal units, gas separation units, gas purification units, heat exchangers, heat recovery units, moisture removal units, catalyst units, chemical injection units, or any
combination thereof), and controls to recirculate the exhaust gas along an exhaust gas circulation path from an output (e.g., discharged exhaust gas 60) to an input (e.g., intake exhaust gas 66) of the SEGR gas turbine system 52. In the illustrated embodiment, the SEGR gas turbine system 52 intakes the exhaust gas 66 into a compressor section having one or more compressors, thereby compressing the exhaust gas 66 for use in a combustor section along with an intake of an oxidant 68 and one or more fuels 70. The oxidant 68 may include ambient air, pure oxygen, oxygen-enriched air, oxygen-reduced air, oxygen-nitrogen mixtures, or any suitable oxidant that facilitates combustion of the fuel 70. The fuel 70 may include one or more gas fuels, liquid fuels, or any combination thereof. For example, the fuel 70 may include natural gas, liquefied natural gas (LNG), syngas, methane, ethane, propane, butane, naphtha, kerosene, diesel fuel, ethanol, methanol, biofuel, or any combination thereof.

[0027] The SEGR gas turbine system 52 mixes and combusts the exhaust gas 66, the oxidant 68, and the fuel 70 in the combustor section, thereby generating hot combustion gases or exhaust gas 60 to drive one or more turbine stages in a turbine section. In certain embodiments, each combustor in the combustor section includes one or more premix fuel nozzles, one or more diffusion fuel nozzles, or any combination thereof. For example, each premix fuel nozzle may be configured to mix the oxidant 68 and the fuel 70 internally within the fuel nozzle and/or partially upstream of the fuel nozzle, thereby injecting an oxidant-fuel mixture from the fuel nozzle into the combustion zone for a premixed combustion (e.g., a premixed flame). By further example, each diffusion fuel nozzle may be configured to isolate the flows of oxidant 68 and fuel 70 within the fuel nozzle, thereby separately injecting the oxidant 68 and the fuel 70 from the fuel nozzle into the combustion zone for diffusion combustion (e.g., a diffusion flame). In particular, the diffusion combustion provided by the diffusion fuel nozzles delays mixing of the oxidant 68 and the fuel 70 until the point of initial combustion, i.e., the flame region. In embodiments employing the diffusion fuel nozzles, the diffusion flame may provide increased flame stability, because the diffusion flame generally forms at the point of stoichiometry between the separate streams of oxidant 68 and fuel 70 (i.e., as the oxidant 68 and fuel 70 are mixing). In certain embodiments, one or more diluents (e.g., the exhaust gas 60,
steam, nitrogen, or another inert gas) may be pre-mixed with the oxidant 68, the fuel 70, or both, in either the diffusion fuel nozzle or the premix fuel nozzle. In addition, one or more diluents (e.g., the exhaust gas 60, steam, nitrogen, or another inert gas) may be injected into the combustor at or downstream from the point of combustion within each combustor. The use of these diluents may help temper the flame (e.g., premix flame or diffusion flame), thereby helping to reduce NOx emissions, such as nitrogen monoxide (NO) and nitrogen dioxide (NO2). Regardless of the type of flame, the combustion produces hot combustion gases or exhaust gas 60 to drive one or more turbine stages. As each turbine stage is driven by the exhaust gas 60, the SEGR gas turbine system 52 generates a mechanical power 72 and/or an electrical power 74 (e.g., via an electrical generator). The system 52 also outputs the exhaust gas 60, and may further output water 64. Again, the water 64 may be a treated water, such as a desalinated water, which may be useful in a variety of applications on-site or off-site.

[0028] Exhaust extraction is also provided by the SEGR gas turbine system 52 using one or more extraction points 76. For example, the illustrated embodiment includes an exhaust gas (EG) supply system 78 having an exhaust gas (EG) extraction system 80 and an exhaust gas (EG) treatment system 82, which receive exhaust gas 42 from the extraction points 76, treat the exhaust gas 42, and then supply or distribute the exhaust gas 42 to various target systems. The target systems may include the EOR system 18 and/or other systems, such as a pipeline 86, a storage tank 88, or a carbon sequestration system 90. The EG extraction system 80 may include one or more conduits, valves, controls, and flow separations, which facilitate isolation of the exhaust gas 42 from the oxidant 68, the fuel 70, and other contaminants, while also controlling the temperature, pressure, and flow rate of the extracted exhaust gas 42. The EG treatment system 82 may include one or more heat exchangers (e.g., heat recovery units such as heat recovery steam generators, condensers, coolers, or heaters), catalyst systems (e.g., oxidation catalyst systems), particulate and/or water removal systems (e.g., gas dehydration units, inertial separators, coalescing filters, water impermeable filters, and other filters), chemical injection systems, solvent based treatment systems (e.g., absorbers, flash tanks, etc.), carbon capture systems, gas separation systems, gas purification systems, and/or a solvent based treatment
system, exhaust gas compressors, any combination thereof. These subsystems of the EG treatment system 82 enable control of the temperature, pressure, flow rate, moisture content (e.g., amount of water removal), particulate content (e.g., amount of particulate removal), and gas composition (e.g., percentage of CO2, N2, etc.).

[0029] The extracted exhaust gas 42 is treated by one or more subsystems of the EG treatment system 82, depending on the target system. For example, the EG treatment system 82 may direct all or part of the exhaust gas 42 through a carbon capture system, a gas separation system, a gas purification system, and/or a solvent based treatment system, which is controlled to separate and purify a carbonaceous gas (e.g., carbon dioxide) 92 and/or nitrogen (N2) 94 for use in the various target systems. For example, embodiments of the EG treatment system 82 may perform gas separation and purification to produce a plurality of different streams 95 of exhaust gas 42, such as a first stream 96, a second stream 97, and a third stream 98. The first stream 96 may have a first composition that is rich in carbon dioxide and/or lean in nitrogen (e.g., a CO2 rich, N2 lean stream). The second stream 97 may have a second composition that has intermediate concentration levels of carbon dioxide and/or nitrogen (e.g., intermediate concentration CO2, N2 stream). The third stream 98 may have a third composition that is lean in carbon dioxide and/or rich in nitrogen (e.g., a CO2 lean, N2 rich stream). Each stream 95 (e.g., 96, 97, and 98) may include a gas dehydration unit, a filter, a gas compressor, or any combination thereof, to facilitate delivery of the stream 95 to a target system. In certain embodiments, the CO2 rich, N2 lean stream 96 may have a CO2 purity or concentration level of greater than approximately 70, 75, 80, 85, 90, 95, 96, 97, 98, or 99 percent by volume, and a N2 purity or concentration level of less than approximately 1, 2, 3, 4, 5, 10, 15, 20, 25, or 30 percent by volume. In contrast, the CO2 lean, N2 rich stream 98 may have a CO2 purity or concentration level of less than approximately 1, 2, 3, 4, 5, 10, 15, 20, 25, or 30 percent by volume, and a N2 purity or concentration level of greater than approximately 70, 75, 80, 85, 90, 95, 96, 97, 98, or 99 percent by volume. The intermediate concentration CO2, N2 stream 97 may have a CO2 purity or concentration level and/or a N2 purity or concentration level of between approximately 30 to 70, 35 to 65, 40 to 60, or 45 to 55 percent by volume. Although the foregoing ranges are
merely non-limiting examples, the CO2 rich, N2 lean stream 96 and the CO2 lean, N2 rich stream 98 may be particularly well suited for use with the EOR system 18 and the other systems 84. However, any of these rich, lean, or intermediate concentration CO2 streams 95 may be used, alone or in various combinations, with the EOR system 18 and the other systems 84. For example, the EOR system 18 and the other systems 84 (e.g., the pipeline 86, storage tank 88, and the carbon sequestration system 90) each may receive one or more CO2 rich, N2 lean streams 96, one or more CO2 lean, N2 rich streams 98, one or more intermediate concentration CO2, N2 streams 97, and one or more untreated exhaust gas 42 streams (i.e., bypassing the EG treatment system 82).

[0030] The EG extraction system 80 extracts the exhaust gas 42 at one or more extraction points 76 along the compressor section, the combustor section, and/or the turbine section, such that the exhaust gas 42 may be used in the EOR system 18 and other systems 84 at suitable temperatures and pressures. The EG extraction system 80 and/or the EG treatment system 82 also may circulate fluid flows (e.g., exhaust gas 42) to and from the EG processing system 54. For example, a portion of the exhaust gas 42 passing through the EG processing system 54 may be extracted by the EG extraction system 80 for use in the EOR system 18 and the other systems 84. In certain embodiments, the EG supply system 78 and the EG processing system 54 may be independent or integral with one another, and thus may use independent or common subsystems. For example, the EG treatment system 82 may be used by both the EG supply system 78 and the EG processing system 54. Exhaust gas 42 extracted from the EG processing system 54 may undergo multiple stages of gas treatment, such as one or more stages of gas treatment in the EG processing system 54 followed by one or more additional stages of gas treatment in the EG treatment system 82.

[0031] At each extraction point 76, the extracted exhaust gas 42 may be substantially free of oxidant 68 and fuel 70 (e.g., unburnt fuel or hydrocarbons) due to substantially stoichiometric combustion and/or gas treatment in the EG processing system 54. Furthermore, depending on the target system, the extracted exhaust gas 42 may undergo further treatment in the EG treatment system 82 of the EG supply system 78, thereby further reducing any residual oxidant 68, fuel 70, or other undesirable products of combustion. For example, either before or after treatment in
the EG treatment system 82, the extracted exhaust gas 42 may have less than 1, 2, 3, 4, or 5 percent by volume of oxidant (e.g., oxygen), unburnt fuel or hydrocarbons (e.g., HCs), nitrogen oxides (e.g., NOx), carbon monoxide (CO), sulfur oxides (e.g., SOx), hydrogen, and other products of incomplete combustion. By further example, either before or after treatment in the EG treatment system 82, the extracted exhaust gas 42 may have less than approximately 10, 20, 30, 40, 50, 60, 70, 80, 90, 100, 200, 300, 400, 500, 1000, 2000, 3000, 4000, or 5000 parts per million by volume (ppmv) of oxidant (e.g., oxygen), unburnt fuel or hydrocarbons (e.g., HCs), nitrogen oxides (e.g., NOx), carbon monoxide (CO), sulfur oxides (e.g., SOx), hydrogen, and other products of incomplete combustion. Thus, the exhaust gas 42 is particularly well suited for use with the EOR system 18.

[0032] The EGR operation of the turbine system 52 specifically enables the exhaust extraction at a multitude of locations 76. For example, the compressor section of the system 52 may be used to compress the exhaust gas 66 without any oxidant 68 (i.e., only compression of the exhaust gas 66), such that a substantially oxygen-free exhaust gas 42 may be extracted from the compressor section and/or the combustor section prior to entry of the oxidant 68 and the fuel 70. The extraction points 76 may be located at interstage ports between adjacent compressor stages, at ports along the compressor discharge casing, at ports along each combustor in the combustor section, or any combination thereof. In certain embodiments, the exhaust gas 66 may not mix with the oxidant 68 and fuel 70 until it reaches the head end portion and/or fuel nozzles of each combustor in the combustor section. Furthermore, one or more flow separators (e.g., walls, dividers, baffles, or the like) may be used to isolate the oxidant 68 and the fuel 70 from the extraction points 76. With these flow separators, the extraction points 76 may be disposed directly along a wall of each combustor in the combustor section.

[0033] Once the exhaust gas 66, oxidant 68, and fuel 70 flow through the head end portion (e.g., through fuel nozzles) into the combustion portion (e.g., combustion chamber) of each combustor, the SEGR gas turbine system 52 is controlled to provide a substantially stoichiometric combustion of the exhaust gas 66, oxidant 68, and fuel 70. For example, the system 52 may maintain an equivalence ratio of approximately
0.95 to approximately 1.05. As a result, the products of combustion of the mixture of exhaust gas 66, oxidant 68, and fuel 70 in each combustor is substantially free of oxygen and unburnt fuel. Thus, the products of combustion (or exhaust gas) may be extracted from the turbine section of the SEGR gas turbine system 52 for use as the exhaust gas 42 routed to the EOR system 18. Along the turbine section, the extraction points 76 may be located at any turbine stage, such as interstage ports between adjacent turbine stages. Thus, using any of the foregoing extraction points 76, the turbine-based service system 14 may generate, extract, and deliver the exhaust gas 42 to the hydrocarbon production system 12 (e.g., the EOR system 18) for use in the production of oil/gas 48 from the subterranean reservoir 20.

[0034] FIG. 2 is a diagram of an embodiment of the system 10 of FIG. 1, illustrating a control system 100 coupled to the turbine-based service system 14 and the hydrocarbon production system 12. In the illustrated embodiment, the turbine-based service system 14 includes a combined cycle system 102, which includes the SEGR gas turbine system 52 as a topping cycle, a steam turbine 104 as a bottoming cycle, and the HRSG 56 to recover heat from the exhaust gas 60 to generate the steam 62 for driving the steam turbine 104. Again, the SEGR gas turbine system 52 receives, mixes, and stoichiometrically combusts the exhaust gas 66, the oxidant 68, and the fuel 70 (e.g., premix and/or diffusion flames), thereby producing the exhaust gas 60, the mechanical power 72, the electrical power 74, and/or the water 64. For example, the SEGR gas turbine system 52 may drive one or more loads or machinery 106, such as an electrical generator, an oxidant compressor (e.g., a main air compressor), a gear box, a pump, equipment of the hydrocarbon production system 12, or any combination thereof. In some embodiments, the machinery 106 may include other drives, such as electrical motors or steam turbines (e.g., the steam turbine 104), in tandem with the SEGR gas turbine system 52. Accordingly, an output of the machinery 106 driven by the SEGR gas turbines system 52 (and any additional drives) may include the mechanical power 72 and the electrical power 74. The mechanical power 72 and/or the electrical power 74 may be used on-site for powering the hydrocarbon production system 12, the electrical power 74 may be distributed to the power grid, or any combination thereof. The output of the machinery 106 also
may include a compressed fluid, such as a compressed oxidant 68 (e.g., air or oxygen), for intake into the combustion section of the SEGR gas turbine system 52. Each of these outputs (e.g., the exhaust gas 60, the mechanical power 72, the electrical power 74, and/or the water 64) may be considered a service of the turbine-based service system 14.

[0035] The SEGR gas turbine system 52 produces the exhaust gas 42, 60, which may be substantially free of oxygen, and routes this exhaust gas 42, 60 to the EG processing system 54 and/or the EG supply system 78. The EG supply system 78 may treat and delivery the exhaust gas 42 (e.g., streams 95) to the hydrocarbon production system 12 and/or the other systems 84. As discussed above, the EG processing system 54 may include the HRSG 56 and the EGR system 58. The HRSG 56 may include one or more heat exchangers, condensers, and various heat recovery equipment, which may be used to recover or transfer heat from the exhaust gas 60 to water 108 to generate the steam 62 for driving the steam turbine 104. Similar to the SEGR gas turbine system 52, the steam turbine 104 may drive one or more loads or machinery 106, thereby generating the mechanical power 72 and the electrical power 74. In the illustrated embodiment, the SEGR gas turbine system 52 and the steam turbine 104 are arranged in tandem to drive the same machinery 106. However, in other embodiments, the SEGR gas turbine system 52 and the steam turbine 104 may separately drive different machinery 106 to independently generate mechanical power 72 and/or electrical power 74. As the steam turbine 104 is driven by the steam 62 from the HRSG 56, the steam 62 gradually decreases in temperature and pressure. Accordingly, the steam turbine 104 recirculates the used steam 62 and/or water 108 back into the HRSG 56 for additional steam generation via heat recovery from the exhaust gas 60. In addition to steam generation, the HRSG 56, the EGR system 58, and/or another portion of the EG processing system 54 may produce the water 64, the exhaust gas 42 for use with the hydrocarbon production system 12, and the exhaust gas 66 for use as an input into the SEGR gas turbine system 52. For example, the water 64 may be a treated water 64, such as a desalinated water for use in other applications. The desalinated water may be particularly useful in regions of low water availability. Regarding the exhaust gas 60, embodiments of the EG processing system
54 may be configured to recirculate the exhaust gas 60 through the EGR system 58 with or without passing the exhaust gas 60 through the HRSG 56.

[0036] In the illustrated embodiment, the SEGR gas turbine system 52 has an exhaust recirculation path 110, which extends from an exhaust outlet to an exhaust inlet of the system 52. Along the path 110, the exhaust gas 60 passes through the EG processing system 54, which includes the HRSG 56 and the EGR system 58 in the illustrated embodiment. The EGR system 58 may include one or more conduits, valves, blowers, gas treatment systems (e.g., filters, particulate removal units, gas separation units, gas purification units, heat exchangers, heat recovery units such as heat recovery steam generators, moisture removal units, catalyst units, chemical injection units, or any combination thereof) in series and/or parallel arrangements along the path 110. In other words, the EGR system 58 may include any flow control components, pressure control components, temperature control components, moisture control components, and gas composition control components along the exhaust recirculation path 110 between the exhaust outlet and the exhaust inlet of the system 52. Accordingly, in embodiments with the HRSG 56 along the path 110, the HRSG 56 may be considered a component of the EGR system 58. However, in certain embodiments, the HRSG 56 may be disposed along an exhaust path independent from the exhaust recirculation path 110. Regardless of whether the HRSG 56 is along a separate path or a common path with the EGR system 58, the HRSG 56 and the EGR system 58 intake the exhaust gas 60 and output either the recirculated exhaust gas 66, the exhaust gas 42 for use with the EG supply system 78 (e.g., for the hydrocarbon production system 12 and/or other systems 84), or another output of exhaust gas. Again, the SEGR gas turbine system 52 intakes, mixes, and stoichiometrically combusts the exhaust gas 66, the oxidant 68, and the fuel 70 (e.g., premixed and/or diffusion flames) to produce a substantially oxygen-free and fuel-free exhaust gas 60 for distribution to the EG processing system 54, the hydrocarbon production system 12, or other systems 84.

[0037] As noted above with reference to FIG. 1, the hydrocarbon production system 12 may include a variety of equipment to facilitate the recovery or production of oil/gas 48 from a subterranean reservoir 20 through an oil/gas well 26. For
example, the hydrocarbon production system 12 may include the EOR system 18 having the fluid injection system 34. In the illustrated embodiment, the fluid injection system 34 includes an exhaust gas injection EOR system 112 and a steam injection EOR system 114. Although the fluid injection system 34 may receive fluids from a variety of sources, the illustrated embodiment may receive the exhaust gas 42 and the steam 62 from the turbine-based service system 14. The exhaust gas 42 and/or the steam 62 produced by the turbine-based service system 14 also may be routed to the hydrocarbon production system 12 for use in other oil/gas systems 116.

[0038] The quantity, quality, and flow of the exhaust gas 42 and/or the steam 62 may be controlled by the control system 100. The control system 100 may be dedicated entirely to the turbine-based service system 14, or the control system 100 may optionally also provide control (or at least some data to facilitate control) for the hydrocarbon production system 12 and/or other systems 84. In the illustrated embodiment, the control system 100 includes a controller 118 having a processor 120, a memory 122, a steam turbine control 124, a SEGR gas turbine system control 126, and a machinery control 128. The processor 120 may include a single processor or two or more redundant processors, such as triple redundant processors for control of the turbine-based service system 14. The memory 122 may include volatile and/or non-volatile memory. For example, the memory 122 may include one or more hard drives, flash memory, read-only memory, random access memory, or any combination thereof. The controls 124, 126, and 128 may include software and/or hardware controls. For example, the controls 124, 126, and 128 may include various instructions or code stored on the memory 122 and executable by the processor 120. The control 124 is configured to control operation of the steam turbine 104, the SEGR gas turbine system control 126 is configured to control the system 52, and the machinery control 128 is configured to control the machinery 106. Thus, the controller 118 (e.g., controls 124, 126, and 128) may be configured to coordinate various sub-systems of the turbine-based service system 14 to provide a suitable stream of the exhaust gas 42 to the hydrocarbon production system 12.

[0039] In certain embodiments of the control system 100, each element (e.g., system, subsystem, and component) illustrated in the drawings or described herein
includes (e.g., directly within, upstream, or downstream of such element) one or more industrial control features, such as sensors and control devices, which are communicatively coupled with one another over an industrial control network along with the controller 118. For example, the control devices associated with each element may include a dedicated device controller (e.g., including a processor, memory, and control instructions), one or more actuators, valves, switches, and industrial control equipment, which enable control based on sensor feedback 130, control signals from the controller 118, control signals from a user, or any combination thereof. Thus, any of the control functionality described herein may be implemented with control instructions stored and/or executable by the controller 118, dedicated device controllers associated with each element, or a combination thereof.

[0040] In order to facilitate such control functionality, the control system 100 includes one or more sensors distributed throughout the system 10 to obtain the sensor feedback 130 for use in execution of the various controls, e.g., the controls 124, 126, and 128. For example, the sensor feedback 130 may be obtained from sensors distributed throughout the SEGR gas turbine system 52, the machinery 106, the EG processing system 54, the steam turbine 104, the hydrocarbon production system 12, or any other components throughout the turbine-based service system 14 or the hydrocarbon production system 12. For example, the sensor feedback 130 may include temperature feedback, pressure feedback, flow rate feedback, flame temperature feedback, combustion dynamics feedback, intake oxidant composition feedback, intake fuel composition feedback, exhaust composition feedback, the output level of mechanical power 72, the output level of electrical power 74, the output quantity of the exhaust gas 42, 60, the output quantity or quality of the water 64, or any combination thereof. For example, the sensor feedback 130 may include a composition of the exhaust gas 42, 60 to facilitate stoichiometric combustion in the SEGR gas turbine system 52. For example, the sensor feedback 130 may include feedback from one or more intake oxidant sensors along an oxidant supply path of the oxidant 68, one or more intake fuel sensors along a fuel supply path of the fuel 70, and one or more exhaust emissions sensors disposed along the exhaust recirculation path 110 and/or within the SEGR gas turbine system 52. The intake oxidant sensors,
intake fuel sensors, and exhaust emissions sensors may include temperature sensors, pressure sensors, flow rate sensors, and composition sensors. The emissions sensors may includes sensors for nitrogen oxides (e.g., NOX sensors), carbon oxides (e.g., CO sensors and CO2 sensors), sulfur oxides (e.g., SOx sensors), hydrogen (e.g., H2 sensors), oxygen (e.g., O2 sensors), unburnt hydrocarbons (e.g., HC sensors), or other products of incomplete combustion, or any combination thereof.

[0041] Using this feedback 130, the control system 100 may adjust (e.g., increase, decrease, or maintain) the intake flow of exhaust gas 66, oxidant 68, and/or fuel 70 into the SEGR gas turbine system 52 (among other operational parameters) to maintain the equivalence ratio within a suitable range, e.g., between approximately 0.95 to approximately 1.05, between approximately 0.95 to approximately 1.0, between approximately 1.0 to approximately 1.05, or substantially at 1.0. For example, the control system 100 may analyze the feedback 130 to monitor the exhaust emissions (e.g., concentration levels of nitrogen oxides, carbon oxides such as CO and CO2, sulfur oxides, hydrogen, oxygen, unburnt hydrocarbons, and other products of incomplete combustion) and/or determine the equivalence ratio, and then control one or more components to adjust the exhaust emissions (e.g., concentration levels in the exhaust gas 42) and/or the equivalence ratio. The controlled components may include any of the components illustrated and described with reference to the drawings, including but not limited to, valves along the supply paths for the oxidant 68, the fuel 70, and the exhaust gas 66; an oxidant compressor, a fuel pump, or any components in the EG processing system 54; any components of the SEGR gas turbine system 52, or any combination thereof. The controlled components may adjust (e.g., increase, decrease, or maintain) the flow rates, temperatures, pressures, or percentages (e.g., equivalence ratio) of the oxidant 68, the fuel 70, and the exhaust gas 66 that combust within the SEGR gas turbine system 52. The controlled components also may include one or more gas treatment systems, such as catalyst units (e.g., oxidation catalyst units), supplies for the catalyst units (e.g., oxidation fuel, heat, electricity, etc.), gas purification and/or separation units (e.g., solvent based separators, absorbers, flash tanks, etc.), and filtration units. The gas treatment systems may help reduce various
exhaust emissions along the exhaust recirculation path 110, a vent path (e.g., exhausted into the atmosphere), or an extraction path to the EG supply system 78.

[0042] In certain embodiments, the control system 100 may analyze the feedback 130 and control one or more components to maintain or reduce emissions levels (e.g., concentration levels in the exhaust gas 42, 60, 95) to a target range, such as less than approximately 10, 20, 30, 40, 50, 100, 200, 300, 400, 500, 1000, 2000, 3000, 4000, 5000, or 10000 parts per million by volume (ppmv). These target ranges may be the same or different for each of the exhaust emissions, e.g., concentration levels of nitrogen oxides, carbon monoxide, sulfur oxides, hydrogen, oxygen, unburnt hydrocarbons, and other products of incomplete combustion. For example, depending on the equivalence ratio, the control system 100 may selectively control exhaust emissions (e.g., concentration levels) of oxidant (e.g., oxygen) within a target range of less than approximately 10, 20, 30, 40, 50, 60, 70, 80, 90, 100, 250, 500, 750, or 1000 ppmv; carbon monoxide (CO) within a target range of less than approximately 20, 50, 100, 200, 500, 1000, 2500, or 5000 ppmv; and nitrogen oxides (NOx) within a target range of less than approximately 50, 100, 200, 300, 400, or 500 ppmv. In certain embodiments operating with a substantially stoichiometric equivalence ratio, the control system 100 may selectively control exhaust emissions (e.g., concentration levels) of oxidant (e.g., oxygen) within a target range of less than approximately 10, 20, 30, 40, 50, 60, 70, 80, 90, or 100 ppmv; and carbon monoxide (CO) within a target range of less than approximately 500, 1000, 2000, 3000, 4000, or 5000 ppmv. In certain embodiments operating with a fuel-lean equivalence ratio (e.g., between approximately 0.95 to 1.0), the control system 100 may selectively control exhaust emissions (e.g., concentration levels) of oxidant (e.g., oxygen) within a target range of less than approximately 500, 600, 700, 800, 900, 1000, 1100, 1200, 1300, 1400, or 1500 ppmv; carbon monoxide (CO) within a target range of less than approximately 10, 20, 30, 40, 50, 60, 70, 80, 90, 100, 150, or 200 ppmv; and nitrogen oxides (e.g., NOx) within a target range of less than approximately 50, 100, 150, 200, 250, 300, 350, or 400 ppmv. The foregoing target ranges are merely examples, and are not intended to limit the scope of the disclosed embodiments.
The control system 100 also may be coupled to a local interface 132 and a remote interface 134. For example, the local interface 132 may include a computer workstation disposed on-site at the turbine-based service system 14 and/or the hydrocarbon production system 12. In contrast, the remote interface 134 may include a computer workstation disposed off-site from the turbine-based service system 14 and the hydrocarbon production system 12, such as through an internet connection. These interfaces 132 and 134 facilitate monitoring and control of the turbine-based service system 14, such as through one or more graphical displays of sensor feedback 130, operational parameters, and so forth.

Again, as noted above, the controller 118 includes a variety of controls 124, 126, and 128 to facilitate control of the turbine-based service system 14. The steam turbine control 124 may receive the sensor feedback 130 and output control commands to facilitate operation of the steam turbine 104. For example, the steam turbine control 124 may receive the sensor feedback 130 from the HRSG 56, the machinery 106, temperature and pressure sensors along a path of the steam 62, temperature and pressure sensors along a path of the water 108, and various sensors indicative of the mechanical power 72 and the electrical power 74. Likewise, the SEGR gas turbine system control 126 may receive sensor feedback 130 from one or more sensors disposed along the SEGR gas turbine system 52, the machinery 106, the EG processing system 54, or any combination thereof. For example, the sensor feedback 130 may be obtained from temperature sensors, pressure sensors, clearance sensors, vibration sensors, flame sensors, fuel composition sensors, exhaust gas composition sensors, or any combination thereof, disposed within or external to the SEGR gas turbine system 52. Finally, the machinery control 128 may receive sensor feedback 130 from various sensors associated with the mechanical power 72 and the electrical power 74, as well as sensors disposed within the machinery 106. Each of these controls 124, 126, and 128 uses the sensor feedback 130 to improve operation of the turbine-based service system 14.

In the illustrated embodiment, the SEGR gas turbine system control 126 may execute instructions to control the quantity and quality of the exhaust gas 42, 60, 95 in the EG processing system 54, the EG supply system 78, the hydrocarbon
production system 12, and/or the other systems 84. For example, the SEGR gas
turbine system control 126 may maintain a level of oxidant (e.g., oxygen) and/or
unburnt fuel in the exhaust gas 60 below a threshold suitable for use with the exhaust
gas injection EOR system 112. In certain embodiments, the threshold levels may be
less than 1, 2, 3, 4, or 5 percent of oxidant (e.g., oxygen) and/or unburnt fuel by
volume of the exhaust gas 42, 60; or the threshold levels of oxidant (e.g., oxygen)
and/or unburnt fuel (and other exhaust emissions) may be less than approximately 10,
20, 30, 40, 50, 60, 70, 80, 90, 100, 200, 300, 400, 500, 1000, 2000, 3000, 4000, or
5000 parts per million by volume (ppmv) in the exhaust gas 42, 60. By further
example, in order to achieve these low levels of oxidant (e.g., oxygen) and/or unburnt
fuel, the SEGR gas turbine system control 126 may maintain an equivalence ratio for
combustion in the SEGR gas turbine system 52 between approximately 0.95 and
approximately 1.05. The SEGR gas turbine system control 126 also may control the
EG extraction system 80 and the EG treatment system 82 to maintain the temperature,
pressure, flow rate, and gas composition of the exhaust gas 42, 60, 95 within suitable
ranges for the exhaust gas injection EOR system 112, the pipeline 86, the storage tank
88, and the carbon sequestration system 90. As discussed above, the EG treatment
system 82 may be controlled to purify and/or separate the exhaust gas 42 into one or
more gas streams 95, such as the CO2 rich, N2 lean stream 96, the intermediate
concentration CO2, N2 stream 97, and the CO2 lean, N2 rich stream 98. In addition to
controls for the exhaust gas 42, 60, and 95, the controls 124, 126, and 128 may
execute one or more instructions to maintain the mechanical power 72 within a
suitable power range, or maintain the electrical power 74 within a suitable frequency
and power range.

[0046] FIG. 3 is a diagram of embodiment of the system 10, further illustrating
details of the SEGR gas turbine system 52 for use with the hydrocarbon production
system 12 and/or other systems 84. In the illustrated embodiment, the SEGR gas
turbine system 52 includes a gas turbine engine 150 coupled to the EG processing
system 54. The illustrated gas turbine engine 150 includes a compressor section 152, a
combustor section 154, and an expander section or turbine section 156. The
compressor section 152 includes one or more exhaust gas compressors or compressor
stages 158, such as 1 to 20 stages of rotary compressor blades disposed in a series arrangement. Likewise, the combustor section 154 includes one or more combustors 160, such as 1 to 20 combustors 160 distributed circumferentially about a rotational axis 162 of the SEGR gas turbine system 52. Furthermore, each combustor 160 may include one or more fuel nozzles 164 configured to inject the exhaust gas 66, the oxidant 68, and/or the fuel 70. For example, a head end portion 166 of each combustor 160 may house 1, 2, 3, 4, 5, 6, or more fuel nozzles 164, which may inject streams or mixtures of the exhaust gas 66, the oxidant 68, and/or the fuel 70 into a combustion portion 168 (e.g., combustion chamber) of the combustor 160.

[0047] The fuel nozzles 164 may include any combination of premix fuel nozzles 164 (e.g., configured to premix the oxidant 68 and fuel 70 for generation of an oxidant/fuel premix flame) and/or diffusion fuel nozzles 164 (e.g., configured to inject separate flows of the oxidant 68 and fuel 70 for generation of an oxidant/fuel diffusion flame). Embodiments of the premix fuel nozzles 164 may include swirl vanes, mixing chambers, or other features to internally mix the oxidant 68 and fuel 70 within the nozzles 164, prior to injection and combustion in the combustion chamber 168. The premix fuel nozzles 164 also may receive at least some partially mixed oxidant 68 and fuel 70. In certain embodiments, each diffusion fuel nozzle 164 may isolate flows of the oxidant 68 and the fuel 70 until the point of injection, while also isolating flows of one or more diluents (e.g., the exhaust gas 66, steam, nitrogen, or another inert gas) until the point of injection. In other embodiments, each diffusion fuel nozzle 164 may isolate flows of the oxidant 68 and the fuel 70 until the point of injection, while partially mixing one or more diluents (e.g., the exhaust gas 66, steam, nitrogen, or another inert gas) with the oxidant 68 and/or the fuel 70 prior to the point of injection. In addition, one or more diluents (e.g., the exhaust gas 66, steam, nitrogen, or another inert gas) may be injected into the combustor (e.g., into the hot products of combustion) either at or downstream from the combustion zone, thereby helping to reduce the temperature of the hot products of combustion and reduce emissions of NOX (e.g., NO and NO2). Regardless of the type of fuel nozzle 164, the SEGR gas turbine system 52 may be controlled to provide substantially stoichiometric combustion of the oxidant 68 and fuel 70.
In diffusion combustion embodiments using the diffusion fuel nozzles 164, the fuel 70 and oxidant 68 generally do not mix upstream from the diffusion flame, but rather the fuel 70 and oxidant 68 mix and react directly at the flame surface and/or the flame surface exists at the location of mixing between the fuel 70 and oxidant 68. In particular, the fuel 70 and oxidant 68 separately approach the flame surface (or diffusion boundary/interface), and then diffuse (e.g., via molecular and viscous diffusion) along the flame surface (or diffusion boundary/interface) to generate the diffusion flame. It is noteworthy that the fuel 70 and oxidant 68 may be at a substantially stoichiometric ratio along this flame surface (or diffusion boundary/interface), which may result in a greater flame temperature (e.g., a peak flame temperature) along this flame surface. The stoichiometric fuel/oxidant ratio generally results in a greater flame temperature (e.g., a peak flame temperature), as compared with a fuel-lean or fuel-rich fuel/oxidant ratio. As a result, the diffusion flame may be substantially more stable than a premix flame, because the diffusion of fuel 70 and oxidant 68 helps to maintain a stoichiometric ratio (and greater temperature) along the flame surface. Although greater flame temperatures can also lead to greater exhaust emissions, such as NOX emissions, the disclosed embodiments use one or more diluents to help control the temperature and emissions while still avoiding any premixing of the fuel 70 and oxidant 68. For example, the disclosed embodiments may introduce one or more diluents separate from the fuel 70 and oxidant 68 (e.g., after the point of combustion and/or downstream from the diffusion flame), thereby helping to reduce the temperature and reduce the emissions (e.g., NOX emissions) produced by the diffusion flame.

In operation, as illustrated, the compressor section 152 receives and compresses the exhaust gas 66 from the EG processing system 54, and outputs a compressed exhaust gas 170 to each of the combustors 160 in the combustor section 154. Upon combustion of the fuel 60, oxidant 68, and exhaust gas 170 within each combustor 160, additional exhaust gas or products of combustion 172 (i.e., combustion gas) is routed into the turbine section 156. Similar to the compressor section 152, the turbine section 156 includes one or more turbines or turbine stages 174, which may include a series of rotary turbine blades. These turbine blades are
then driven by the products of combustion 172 generated in the combustor section 154, thereby driving rotation of a shaft 176 coupled to the machinery 106. Again, the machinery 106 may include a variety of equipment coupled to either end of the SEGR gas turbine system 52, such as machinery 106, 178 coupled to the turbine section 156 and/or machinery 106, 180 coupled to the compressor section 152. In certain embodiments, the machinery 106, 178, 180 may include one or more electrical generators, oxidant compressors for the oxidant 68, fuel pumps for the fuel 70, gear boxes, or additional drives (e.g. steam turbine 104, electrical motor, etc.) coupled to the SEGR gas turbine system 52. Non-limiting examples are discussed in further detail below with reference to TABLE 1. As illustrated, the turbine section 156 outputs the exhaust gas 60 to recirculate along the exhaust recirculation path 110 from an exhaust outlet 182 of the turbine section 156 to an exhaust inlet 184 into the compressor section 152. Along the exhaust recirculation path 110, the exhaust gas 60 passes through the EG processing system 54 (e.g., the HRSG 56 and/or the EGR system 58) as discussed in detail above.

[0050] Again, each combustor 160 in the combustor section 154 receives, mixes, and stoichiometrically combusts the compressed exhaust gas 170, the oxidant 68, and the fuel 70 to produce the additional exhaust gas or products of combustion 172 to drive the turbine section 156. In certain embodiments, the oxidant 68 is compressed by an oxidant compression system 186, such as a main oxidant compression (MOC) system (e.g., a main air compression (MAC) system) having one or more oxidant compressors (MOCs). The oxidant compression system 186 includes an oxidant compressor 188 coupled to a drive 190. For example, the drive 190 may include an electric motor, a combustion engine, or any combination thereof. In certain embodiments, the drive 190 may be a turbine engine, such as the gas turbine engine 150. Accordingly, the oxidant compression system 186 may be an integral part of the machinery 106. In other words, the compressor 188 may be directly or indirectly driven by the mechanical power 72 supplied by the shaft 176 of the gas turbine engine 150. In such an embodiment, the drive 190 may be excluded, because the compressor 188 relies on the power output from the turbine engine 150. However, in certain embodiments employing more than one oxidant compressor is employed, a first
oxidant compressor (e.g., a low pressure (LP) oxidant compressor) may be driven by the drive 190 while the shaft 176 drives a second oxidant compressor (e.g., a high pressure (HP) oxidant compressor), or vice versa. For example, in another embodiment, the HP MOC is driven by the drive 190 and the LP oxidant compressor is driven by the shaft 176. In the illustrated embodiment, the oxidant compression system 186 is separate from the machinery 106. In each of these embodiments, the compression system 186 compresses and supplies the oxidant 68 to the fuel nozzles 164 and the combustors 160. Accordingly, some or all of the machinery 106, 178, 180 may be configured to increase the operational efficiency of the compression system 186 (e.g., the compressor 188 and/or additional compressors).

[0051] The variety of components of the machinery 106, indicated by element numbers 106A, 106B, 106C, 106D, 106E, and 106F, may be disposed along the line of the shaft 176 and/or parallel to the line of the shaft 176 in one or more series arrangements, parallel arrangements, or any combination of series and parallel arrangements. For example, the machinery 106, 178, 180 (e.g., 106A through 106F) may include any series and/or parallel arrangement, in any order, of: one or more gearboxes (e.g., parallel shaft, epicyclic gearboxes), one or more compressors (e.g., oxidant compressors, booster compressors such as EG booster compressors), one or more power generation units (e.g., electrical generators), one or more drives (e.g., steam turbine engines, electrical motors), heat exchange units (e.g., direct or indirect heat exchangers), clutches, or any combination thereof. The compressors may include axial compressors, radial or centrifugal compressors, or any combination thereof, each having one or more compression stages. Regarding the heat exchangers, direct heat exchangers may include spray coolers (e.g., spray intercoolers), which inject a liquid spray into a gas flow (e.g., oxidant flow) for direct cooling of the gas flow. Indirect heat exchangers may include at least one wall (e.g., a shell and tube heat exchanger) separating first and second flows, such as a fluid flow (e.g., oxidant flow) separated from a coolant flow (e.g., water, air, refrigerant, or any other liquid or gas coolant), wherein the coolant flow transfers heat from the fluid flow without any direct contact. Examples of indirect heat exchangers include intercooler heat exchangers and heat recovery units, such as heat recovery steam generators. The heat exchangers also may
include heaters. As discussed in further detail below, each of these machinery components may be used in various combinations as indicated by the non-limiting examples set forth in TABLE 1.

[0052] Generally, the machinery 106, 178, 180 may be configured to increase the efficiency of the compression system 186 by, for example, adjusting operational speeds of one or more oxidant compressors in the system 186, facilitating compression of the oxidant 68 through cooling, and/or extraction of surplus power. The disclosed embodiments are intended to include any and all permutations of the foregoing components in the machinery 106, 178, 180 in series and parallel arrangements, wherein one, more than one, all, or none of the components derive power from the shaft 176. As illustrated below, TABLE 1 depicts some non-limiting examples of arrangements of the machinery 106, 178, 180 disposed proximate and/or coupled to the compressor and turbine sections 152, 156.

**TABLE 1**

[0053] As illustrated above in TABLE 1, a cooling unit is represented as CLR, a clutch is represented as CLU, a drive is represented by DRV, a gearbox is represented
as GBX, a generator is represented by GEN, a heating unit is represented by HTR, a main oxidant compressor unit is represented by MOC, with low pressure and high pressure variants being represented as LP MOC and HP MOC, respectively, and a steam generator unit is represented as STGN. Although TABLE 1 illustrates the machinery 106, 178, 180 in sequence toward the compressor section 152 or the turbine section 156, TABLE 1 is also intended to cover the reverse sequence of the machinery 106, 178, 180. In TABLE 1, any cell including two or more components is intended to cover a parallel arrangement of the components. TABLE 1 is not intended to exclude any non-illustrated permutations of the machinery 106, 178, 180. These components of the machinery 106, 178, 180 may enable feedback control of temperature, pressure, and flow rate of the oxidant 68 sent to the gas turbine engine 150. As discussed in further detail below, the oxidant 68 and the fuel 70 may be supplied to the gas turbine engine 150 at locations specifically selected to facilitate isolation and extraction of the compressed exhaust gas 170 without any oxidant 68 or fuel 70 degrading the quality of the exhaust gas 170.

[0054] The EG supply system 78, as illustrated in FIG. 3, is disposed between the gas turbine engine 150 and the target systems (e.g., the hydrocarbon production system 12 and the other systems 84). In particular, the EG supply system 78, e.g., the EG extraction system (EGES) 80, may be coupled to the gas turbine engine 150 at one or more extraction points 76 along the compressor section 152, the combustor section 154, and/or the turbine section 156. For example, the extraction points 76 may be located between adjacent compressor stages, such as 2, 3, 4, 5, 6, 7, 8, 9, or 10 interstage extraction points 76 between compressor stages. Each of these interstage extraction points 76 provides a different temperature and pressure of the extracted exhaust gas 42. Similarly, the extraction points 76 may be located between adjacent turbine stages, such as 2, 3, 4, 5, 6, 7, 8, 9, or 10 interstage extraction points 76 between turbine stages. Each of these interstage extraction points 76 provides a different temperature and pressure of the extracted exhaust gas 42. By further example, the extraction points 76 may be located at a multitude of locations throughout the combustor section 154, which may provide different temperatures, pressures, flow rates, and gas compositions. Each of these extraction points 76 may
include an EG extraction conduit, one or more valves, sensors, and controls, which may be used to selectively control the flow of the extracted exhaust gas 42 to the EG supply system 78.

[0055] The extracted exhaust gas 42, which is distributed by the EG supply system 78, has a controlled composition suitable for the target systems (e.g., the hydrocarbon production system 12 and the other systems 84). For example, at each of these extraction points 76, the exhaust gas 170 may be substantially isolated from injection points (or flows) of the oxidant 68 and the fuel 70. In other words, the EG supply system 78 may be specifically designed to extract the exhaust gas 170 from the gas turbine engine 150 without any added oxidant 68 or fuel 70. Furthermore, in view of the stoichiometric combustion in each of the combustors 160, the extracted exhaust gas 42 may be substantially free of oxygen and fuel. The EG supply system 78 may route the extracted exhaust gas 42 directly or indirectly to the hydrocarbon production system 12 and/or other systems 84 for use in various processes, such as enhanced oil recovery, carbon sequestration, storage, or transport to an offsite location. However, in certain embodiments, the EG supply system 78 includes the EG treatment system (EGTS) 82 for further treatment of the exhaust gas 42, prior to use with the target systems. For example, the EG treatment system 82 may purify and/or separate the exhaust gas 42 into one or more streams 95, such as the CO2 rich, N2 lean stream 96, the intermediate concentration CO2, N2 stream 97, and the CO2 lean, N2 rich stream 98. These treated exhaust gas streams 95 may be used individually, or in any combination, with the hydrocarbon production system 12 and the other systems 84 (e.g., the pipeline 86, the storage tank 88, and the carbon sequestration system 90).

[0056] Similar to the exhaust gas treatments performed in the EG supply system 78, the EG processing system 54 may include a plurality of exhaust gas (EG) treatment components 192, such as indicated by element numbers 194, 196, 198, 200, 202, 204, 206, 208, and 210. These EG treatment components 192 (e.g., 194 through 210) may be disposed along the exhaust recirculation path 110 in one or more series arrangements, parallel arrangements, or any combination of series and parallel arrangements. For example, the EG treatment components 192 (e.g., 194 through 210) may include any series and/or parallel arrangement, in any order, of: one or more heat
exchangers (e.g., heat recovery units such as heat recovery steam generators, condensers, coolers, or heaters), catalyst systems (e.g., oxidation catalyst systems), particulate and/or water removal systems (e.g., inertial separators, coalescing filters, water impermeable filters, and other filters), chemical injection systems, solvent based treatment systems (e.g., absorbers, flash tanks, etc.), carbon capture systems, gas separation systems, gas purification systems, and/or a solvent based treatment system, or any combination thereof. In certain embodiments, the catalyst systems may include an oxidation catalyst, a carbon monoxide reduction catalyst, a nitrogen oxides reduction catalyst, an aluminum oxide, a zirconium oxide, a silicone oxide, a titanium oxide, a platinum oxide, a palladium oxide, a cobalt oxide, or a mixed metal oxide, or a combination thereof. The disclosed embodiments are intended to include any and all permutations of the foregoing components 192 in series and parallel arrangements. As illustrated below, TABLE 2 depicts some non-limiting examples of arrangements of the components 192 along the exhaust recirculation path 110.
As illustrated above in TABLE 2, a catalyst unit is represented by CU, an oxidation catalyst unit is represented by OCU, a booster blower is represented by BB, a heat exchanger is represented by HX, a heat recovery unit is represented by HRU, a heat recovery steam generator is represented by HRSG, a condenser is represented by COND, a steam turbine is represented by ST, a particulate removal unit is represented by PRU, a moisture removal unit is represented by MRU, a filter is represented by CFIL.
FIL, a coalescing filter is represented by CFIL, a water impermeable filter is represented by WFIL, an inertial separator is represented by INER, and a diluent supply system (e.g., steam, nitrogen, or other inert gas) is represented by DIL. Although TABLE 2 illustrates the components 192 in sequence from the exhaust outlet 182 of the turbine section 156 toward the exhaust inlet 184 of the compressor section 152, TABLE 2 is also intended to cover the reverse sequence of the illustrated components 192. In TABLE 2, any cell including two or more components is intended to cover an integrated unit with the components, a parallel arrangement of the components, or any combination thereof. Furthermore, in context of TABLE 2, the HRU, the HRSG, and the COND are examples of the HE; the HRSG is an example of the HRU; the COND, WFIL, and CFIL are examples of the WRU; the TNER, FIL, WFIL, and CFIL are examples of the PRU; and the WFIL and CFIL are examples of the FIL. Again, TABLE 2 is not intended to exclude any non-illustrated permutations of the components 192. In certain embodiments, the illustrated components 192 (e.g., 194 through 210) may be partially or completed integrated within the HRSG 56, the EGR system 58, or any combination thereof. These EG treatment components 192 may enable feedback control of temperature, pressure, flow rate, and gas composition, while also removing moisture and particulates from the exhaust gas 60. Furthermore, the treated exhaust gas 60 may be extracted at one or more extraction points 76 for use in the EG supply system 78 and/or recirculated to the exhaust inlet 184 of the compressor section 152.

[0058] As the treated, recirculated exhaust gas 66 passes through the compressor section 152, the SEGR gas turbine system 52 may bleed off a portion of the compressed exhaust gas along one or more lines 212 (e.g., bleed conduits or bypass conduits). Each line 212 may route the exhaust gas into one or more heat exchangers 214 (e.g., cooling units), thereby cooling the exhaust gas for recirculation back into the SEGR gas turbine system 52. For example, after passing through the heat exchanger 214, a portion of the cooled exhaust gas may be routed to the turbine section 156 along line 212 for cooling and/or sealing of the turbine casing, turbine shrouds, bearings, and other components. In such an embodiment, the SEGR gas turbine system 52 does not route any oxidant 68 (or other potential contaminants)
through the turbine section 156 for cooling and/or sealing purposes, and thus any
leakage of the cooled exhaust gas will not contaminate the hot products of combustion
(e.g., working exhaust gas) flowing through and driving the turbine stages of the
turbine section 156. By further example, after passing through the heat exchanger
214, a portion of the cooled exhaust gas may be routed along line 216 (e.g., return
conduit) to an upstream compressor stage of the compressor section 152, thereby
improving the efficiency of compression by the compressor section 152. In such an
embodiment, the heat exchanger 214 may be configured as an interstage cooling unit
for the compressor section 152. In this manner, the cooled exhaust gas helps to
increase the operational efficiency of the SEGR gas turbine system 52, while
simultaneously helping to maintain the purity of the exhaust gas (e.g., substantially
free of oxidant and fuel).

[0059] FIG. 4 is a flow chart of an embodiment of an operational process 220 of
the system 10 illustrated in FIGS. 1-3. In certain embodiments, the process 220 may be
a computer implemented process, which accesses one or more instructions stored on
the memory 122 and executes the instructions on the processor 120 of the controller
118 shown in FIG. 2. For example, each step in the process 220 may include
instructions executable by the controller 118 of the control system 100 described with
reference to FIG. 2.

[0060] The process 220 may begin by initiating a startup mode of the SEGR gas
turbine system 52 of FIGS. 1-3, as indicated by block 222. For example, the startup
mode may involve a gradual ramp up of the SEGR gas turbine system 52 to maintain
thermal gradients, vibration, and clearance (e.g., between rotating and stationary
parts) within acceptable thresholds. For example, during the startup mode 222, the
process 220 may begin to supply a compressed oxidant 68 to the combustors 160 and
the fuel nozzles 164 of the combustor section 154, as indicated by block 224. In
certain embodiments, the compressed oxidant may include a compressed air, oxygen,
oxygen-enriched air, oxygen-reduced air, oxygen-nitrogen mixtures, or any
combination thereof. For example, the oxidant 68 may be compressed by the oxidant
compression system 186 illustrated in FIG. 3. The process 220 also may begin to
supply fuel to the combustors 160 and the fuel nozzles 164 during the startup mode
During the startup mode 222, the process 220 also may begin to supply exhaust gas (as available) to the combustors 160 and the fuel nozzles 164, as indicated by block 228. For example, the fuel nozzles 164 may produce one or more diffusion flames, premix flames, or a combination of diffusion and premix flames. During the startup mode 222, the exhaust gas 60 being generated by the gas turbine engine 156 may be insufficient or unstable in quantity and/or quality. Accordingly, during the startup mode, the process 220 may supply the exhaust gas 66 from one or more storage units (e.g., storage tank 88), the pipeline 86, other SEGR gas turbine systems 52, or other exhaust gas sources.

The process 220 may then combust a mixture of the compressed oxidant, fuel, and exhaust gas in the combustors 160 to produce hot combustion gas 172, as indicated by block 230. In particular, the process 220 may be controlled by the control system 100 of FIG. 2 to facilitate stoichiometric combustion (e.g., stoichiometric diffusion combustion, premix combustion, or both) of the mixture in the combustors 160 of the combustor section 154. However, during the startup mode 222, it may be particularly difficult to maintain stoichiometric combustion of the mixture (and thus low levels of oxidant and unburnt fuel may be present in the hot combustion gas 172). As a result, in the startup mode 222, the hot combustion gas 172 may have greater amounts of residual oxidant 68 and/or fuel 70 than during a steady state mode as discussed in further detail below. For this reason, the process 220 may execute one or more control instructions to reduce or eliminate the residual oxidant 68 and/or fuel 70 in the hot combustion gas 172 during the startup mode.

The process 220 then drives the turbine section 156 with the hot combustion gas 172, as indicated by block 232. For example, the hot combustion gas 172 may drive one or more turbine stages 174 disposed within the turbine section 156. Downstream of the turbine section 156, the process 220 may treat the exhaust gas 60 from the final turbine stage 174, as indicated by block 234. For example, the exhaust gas treatment 234 may include filtration, catalytic reaction of any residual oxidant 68 and/or fuel 70, chemical treatment, heat recovery with the HRSG 56, and so forth. The process 220 may also recirculate at least some of the exhaust gas 60 back to the compressor section 152 of the SEGR gas turbine system 52, as indicated by block
For example, the exhaust gas recirculation 236 may involve passage through the exhaust recirculation path 110 having the EG processing system 54 as illustrated in FIGS. 1-3.

[0063] In turn, the recirculated exhaust gas 66 may be compressed in the compressor section 152, as indicated by block 238. For example, the SEGR gas turbine system 52 may sequentially compress the recirculated exhaust gas 66 in one or more compressor stages 158 of the compressor section 152. Subsequently, the compressed exhaust gas 170 may be supplied to the combustors 160 and fuel nozzles 164, as indicated by block 228. Steps 230, 232, 234, 236, and 238 may then repeat, until the process 220 eventually transitions to a steady state mode, as indicated by block 240. Upon the transition 240, the process 220 may continue to perform the steps 224 through 238, but may also begin to extract the exhaust gas 42 via the EG supply system 78, as indicated by block 242. For example, the exhaust gas 42 may be extracted from one or more extraction points 76 along the compressor section 152, the combustor section 154, and the turbine section 156 as indicated in FIG. 3. In turn, the process 220 may supply the extracted exhaust gas 42 from the EG supply system 78 to the hydrocarbon production system 12, as indicated by block 244. The hydrocarbon production system 12 may then inject the exhaust gas 42 into the earth 32 for enhanced oil recovery, as indicated by block 246. For example, the extracted exhaust gas 42 may be used by the exhaust gas injection EOR system 112 of the EOR system 18 illustrated in FIGS. 1-3.

[0064] FIG. 5 is a cutaway side view of an embodiment of the combustor section 154 of the gas turbine engine 150, as illustrated in FIG. 3. As illustrated, one or more fuel nozzles 164 are located inside the combustor 160. In certain embodiments, each fuel nozzle 164 is configured to partially premix the compressed exhaust gas 170, oxidant 68, and fuel 70 within intermediate or interior walls of the fuel nozzles 164 (e.g., using premix fuel nozzles). For example, each fuel nozzle 164 may divert fuel 70 into passages containing the compressed exhaust gas 170 and the oxidant 68, thereby partially premixing a portion of the fuel 70 with the compressed exhaust gas 170 and the oxidant 68 to reduce high temperature zones and nitrogen oxide (NOx) emissions. Further, the fuel nozzles 164 may inject a mixture of the compressed
exhaust gas 170, oxidant 68, and fuel 70 into the combustor 160 in a suitable ratio for optimal combustion, emissions, fuel consumption, and power output (e.g., stoichiometric combustion). In other embodiments, the fuel nozzles 164 may isolate the flows of oxidant 68 and fuel 70 within the fuel nozzle (e.g., using diffusion fuel nozzles), thereby separately injecting the oxidant 68 and the fuel 70 from the fuel nozzle into the combustion zone for diffusion combustion (e.g., a diffusion flame).

[0065] As illustrated in FIG. 5, the plurality of fuel nozzles 164 is attached to an end cover 260, near the head end portion 166 of the combustor 160. The fuel 70 is directed through the end cover 260 and the head end portion 166 to each of the fuel nozzles 164, which distribute the mixture of the compressed exhaust gas 170, oxidant 68, and fuel 70 into the combustion portion 168 of the combustor 160. The combustion portion 168 is generally defined by a first wall 264 about a combustion chamber 262, a second wall 266 disposed about the first wall 264, and a third wall 268 (e.g., outer sleeve) disposed about the second wall 266. Thus, the combustor 160 may be referred to as a triple-wall combustor or multi-wall combustor with at least one of the first, second, and third walls 264, 266, and 268 configured to pass the compressed exhaust gas 170, as described in detail below. The combustor section 154 also includes a compressor discharge casing or combustor casting 270 disposed about the third wall 268 of the combustor 160. As shown in FIG. 5, the first wall 264 extends circumferentially about (with a radial offset relative to) the combustion chamber 262, the second wall 266 extends circumferentially about (with a radial offset relative to) the first wall 264, the third wall 268 extends circumferentially about (with a radial offset relative to) the second wall 266, and the combustion casing 270 extends circumferentially about (with a radial offset relative to) the third wall 268. In certain embodiments, the second wall 266 and the third wall 268 are coaxial with one another to define a first space 272 (e.g., annular passage), which may enable passage of the oxidant 68 to be mixed with the compressed exhaust gas 170. Specifically, the third wall 268 may include at least one oxidant port 274 to direct the oxidant 68 into the first space 272. In addition, at least one oxidant conduit 276 may extend through the casing 270 of the combustor section 154 to the at least one oxidant port 274. The oxidant conduit 276 may direct the oxidant 68 (e.g., ambient air, pure oxygen,
oxygen-enriched air, oxygen-reduced air, or oxygen-nitrogen mixtures) from a source of oxidant 68 (e.g., oxidant compression system 186) to the oxidant port 274. In addition, the oxidant conduit 276 may segregate the oxidant 68 from the compressed exhaust gas 170 outside of the third wall 268.

[0066] In addition, the third wall 268 may include at least one exhaust gas port 278 to direct the compressed exhaust gas 170 into the first space 272. Thus, the oxidant 68 and the compressed exhaust gas 170 are supplied independently into the third wall 268. In certain embodiments, the third wall 268 includes a plurality of exhaust gas ports 278, as shown in FIG. 5. Each of the plurality of exhaust gas ports 278 may enable the compressed exhaust gas 170 to gradually combine with the oxidant 68 to create an oxidant-exhaust gas mixture 280 flowing though the first space 272. In certain embodiments, the number, size, and/or arrangement of the exhaust gas ports 278 may be adjusted to achieve a desired mixing of the oxidant 68 and the compressed exhaust gas 170 in the first space 272. For example, increasing the number of exhaust gas ports 278 may result in the oxidant-exhaust gas mixture 280 having a higher concentration of the compressed exhaust gas 170. In addition, a first distance 282 between the second wall 266 and the third wall 268 may be adjusted to achieve a desired flow rate of the oxidant-exhaust gas mixture 280 through the first space 272. For example, increasing the first distance 282 may increase the flow rate of the oxidant-exhaust gas mixture 280.

[0067] As shown in FIG. 5, the one or more exhaust gas ports 278 are disposed downstream from the oxidant port 274 relative to the flow of oxidant 68 into the combustor 160. In addition, a first pressure of the oxidant 68 received at the oxidant port 274 may be less than a second pressure of the compressed exhaust gas 170 received at the exhaust gas ports 278. Thus, the pressure of the compressed exhaust gas 170 between the third wall 268 and combustion casing 270 may be greater than a pressure of the oxidant-exhaust gas mixture 280 in the first space 272. Accordingly, any leakage caused by the third wall 268 may tend to be in the direction into the first space 272, thereby helping to block the oxidant 68 from mixing with the compressed exhaust gas 170 between the third wall 268 and combustion casing 270. As certain applications use compressed exhaust gas 170 that is substantially free of oxidant 68,
the arrangement of the oxidant port 274 upstream of the exhaust gas ports 278 and the
control of the pressure of the first space 272 may be used to help exclude the oxidant
68 from the compressed exhaust gas 170 at an exhaust gas extraction port 312.

[0068] As illustrated in FIG. 5, the oxidant-exhaust gas mixture 280 may flow
through the first space 272 away from the head end portion 166. In addition, the
second wall 266 may include at least one impingement cooling orifice 284 located
away from the head end portion 166. In other words, the at least one impingement
cooling orifice 284 may be disposed near the turbine stages 174 (e.g., near the
forward end of the combustor 160). In certain embodiments, the second wall 266 may
include a plurality of impingement cooling orifices 284 (e.g., 10 to 1000 orifices) to
provide impingement cooling of the first wall 264, for example, by impinging jets of
the mixture 280 against the outer surface of the first wall 264. Thus, the impingement
cooling orifices 284 enable the oxidant-exhaust gas mixture 280 to enter a second
space 286 (e.g., annular passage), between the first and second walls 264 and 266,
which may be coaxial with one another in certain embodiments. The impingement
cooling orifices 284 also enable the oxidant-exhaust gas mixture 280 to reverse
direction from a first path 288 in the first space 272 to a second path 290 in the second
space 286. In other words, the first path 288 flows in the direction from the head end
portion 166 toward the turbine stages 174, and the second path 290 flows in the
direction from the turbine stages 174 toward the head end portion 166. Once inside
the second space 286, the oxidant-exhaust gas mixture 280 flows along the first wall
264, thereby providing convective cooling of the outer surface of the first wall 264
opposite from an inner surface exposed to the combustion gas 172.

[0069] In certain embodiments, a first portion of the second wall 266 may be
referred to as a flow sleeve 292 and a second portion of the second wall 266 may be
referred to as an impingement sleeve 294. Specifically, the flow sleeve 292 may be
located near the head end portion 166, and the impingement sleeve 294 may be
located near the turbine stages 174. Similarly, a first portion of the first wall 264 may
be referred to as a combustion liner 296, and a second portion of the first wall 264
may be referred to as a transition piece 298. Specifically, the combustion liner 296
may be located near the head end potion 166 and the transition piece 298 may be
located near the turbine stages 174. Thus, the plurality of impingement cooling orifices 284 may be formed in the impingement sleeve 294 to help provide cooling of the transition piece 298. In certain embodiments, a first hula seal 300 may couple the combustion liner 296 and the transition piece 298. In addition, a second hula seal 302 may couple the flow sleeve 292 and the impingement sleeve 294. In further embodiments, a third hula seal 304 may couple a first portion 306 of the third wall 268 and a second portion 308 of the third wall 268. The first portion 306 may be disposed about the flow sleeve 292 and the second portion 308 may be disposed about the impingement sleeve 294. In some embodiments, other methods or devices may be used to couple the various components of the first, second, and third walls 264, 266, and 268. For example, one or more of the first, second, and third walls 264, 266, and 268 may be made from one piece and not from separate components.

[0070] As the oxidant-exhaust gas mixture 280 flows through the first and second spaces 272 and 286, the oxidant 68 and the compressed exhaust gas 170 continue to mix with one another. Therefore, the combined length of the first and second spaces 272 and 286 provides sufficient mixing length to combine the oxidant 68 and compressed exhaust gas 170, thereby improving performance of the combustor 160. In addition the oxidant-exhaust gas mixture 280 provides cooling to the first wall 264 as the mixture 280 flows through the second space 286. In certain embodiments, as the oxidant-exhaust gas mixture 280 leaves the second space 286, the mixture 280 enters the head end portion 166 to be combined with the fuel 70 in the fuel nozzles 164 (e.g., premix fuel nozzles) to produce a mixture 310 of the fuel 70, oxidant 68, and the compressed exhaust gas 170, which is combusted in the combustion chamber 262 to generate the combustion gas 172. In other embodiments, the mixture 280 entering the head end portion 166 is kept separate from the fuel 70 in the fuel nozzles 164 (e.g., diffusion fuel nozzles). As the combustion gas 172 flows away from the head end portion 166, the gas 172 flows through the combustion liner 296 and the transition piece 298 toward the turbine stages 174.

[0071] In addition, the compressed exhaust gas 170 within the combustion casing 270 may be extracted through the exhaust gas extraction port 312 to be used as the exhaust gas 42 in the exhaust gas supply system 78, as described in detail above.
Specifically, the exhaust gas extraction port 312 is disposed upstream of the exhaust gas ports 278 where the exhaust gas 170 enters the first space 272 and mixes with the oxidant 68. By disposing the exhaust gas extraction port 312 upstream of where the oxidant 68 is added, the extracted exhaust gas 42 is kept free of oxidant 68, which may be important in certain applications, such as the oil/gas extraction system 16 or the EOR system 18.

[0072] FIG. 6 is a cutaway side view of an embodiment of the combustor section 154 with a bypass tube 330. Elements in FIG. 6 in common with those shown in FIG. 5 are labeled with the same reference numerals. As shown in FIG. 6, the exhaust gas extraction port 312 is disposed upstream from the mixing of the compressed exhaust gas 170 with the oxidant 68. In addition, a bypass tube 330 may pass through the first, second, and third walls 264, 266, and 268. The bypass tube 330 may be used to transfer the compressed exhaust gas 170 directly to the combustion chamber 262. The bypass tube 330 may be used when additional diluent (e.g., compressed exhaust gas 170) is used for the combustion in the combustor 160. In certain embodiments, the diluent (e.g., exhaust gas 170) supplied to the combustor 160 through the bypass tube 330 contains substantially no oxygen to help maintain the stoichiometric combustion within the combustor 160. As the compressed exhaust gas 170 contains substantially no oxygen, the compressed exhaust gas 170 may be used as the diluent for the combustor 160. Thus, the bypass tube 330 enables the substantially oxygen-free compressed exhaust gas 170 to be transferred directly into the combustion chamber 262 to be used as the diluent. Accordingly, the compressed exhaust gas 170 transferred through the bypass tube 330 may be used to control and/or adjust the combustion occurring within the combustor 160. For example, by introducing the compressed exhaust gas 170 through the bypass tube 330, the amount of NOₓ and the temperature of the combustion gas 172 may be reduced while still obtaining benefits of stoichiometric combustion. In certain embodiments, a plurality of bypass tubes 330 (e.g., 2, 3, 4, 5, 6, 7, 8, 9, 10, or more) may pass through the first, second, and third walls, 264, 266, and 268. The plurality of bypass tubes 330 may be arranged evenly about the combustor 160 in a circumferential manner, or the bypass tubes 330 may be arranged in a non-uniform manner selected to focus the diluent toward hot spots.
Use of the bypass tube 330 may be desirable when the fuel nozzles 164 are diffusion fuel nozzles. Diffusion flames may help to maintain stability and operation within certain limits for stoichiometric combustion, which in turn helps to increase production of CO$_2$. For example, gas turbine systems operating with diffusion flames may enable a greater quantity of EGR, as compared to gas turbine systems operating with premix flames. In turn, the increased quantity of EGR helps to increase CO$_2$ production. In addition, the fuel 70 and oxidant 68 may be at a substantially stoichiometric ratio along the diffusion flame surface (or diffusion boundary/interface), which may result in a greater flame temperature (e.g., a peak flame temperature) along this flame surface. Although greater flame temperatures can also lead to greater exhaust emissions, such as NO$_X$ emissions, the injection of the exhaust gas 170 through the bypass tube 330 may help control the temperature and emissions while still avoiding any premixing of the fuel 70 and oxidant 68.

FIG. 7 is a cutaway side view of an embodiment of the combustor section 154 that does not include the impingement cooling orifices 284 shown in FIG. 5. Instead, the oxidant-exhaust gas mixture 280 flowing through the first space 272 flows through one or more openings or gaps 340 to enter the second space 286. For example, the impingement sleeve 294 may not extend to couple with the third wall 268. Thus, the impingement sleeve 294 acts as a baffle for cooling of the transition piece 298. As shown in FIG. 7, the oxidant-exhaust gas mixture 280 reverses directions from the first path 288 to the second path 290 as the mixture 280 flows through the gap 340. Thus, the oxidant-exhaust gas mixture 280 provides convective cooling of the first wall 264. By using the gap 340 instead of the plurality of impingement cooling orifices 284 shown in FIG. 5, the construction of the second wall 266 may be simplified. As discussed above, either premix fuel nozzles or diffusion fuel nozzles may be used in the illustrated combustor section 154. In addition, the combustor section 154 may be used for stoichiometric combustion, as discussed above. Further, the exhaust gas extraction port 312 is disposed upstream from the mixing of the compressed exhaust gas 170 with the oxidant 68. Other elements in FIG. 7 in common with those shown in FIG. 5 are labeled with the same reference numerals.
FIG. 8 is a cutaway side view of an embodiment of the combustor section 154 with a bell mouth 350 for the compressed exhaust gas 170. Elements in FIG. 8 in common with those shown in FIG. 5 are labeled with the same reference numerals. As shown in FIG. 8, the bell mouth 350 has a gradually converging shape that helps direct the compressed exhaust gas 170 into the first space 272, thus functioning in a similar manner to the exhaust gas port 278 described above. In certain embodiments, the bell mouth 350 may extend in a continuous circumferential manner. In addition, the third wall 268 extends toward the head end portion 166 by a shorter distance than shown in FIGS. 5-7. Specifically, the third wall 268 includes the bell mouth 350 near the first and second hula seals 300 and 302. In other embodiments, the bell mouth 350 may be located in a different location. The bell mouth 350 may be shaped to guide the compressed exhaust gas 170 into the first space 272. As shown in FIG. 8, the oxidant conduit 276 extends through the combustion casing 270 and the oxidant port 274 is disposed in the third wall 268 downstream from the bell mouth 350 relative to the flow of exhaust gas 170. Thus, the oxidant-exhaust gas mixture 280 is formed downstream of the oxidant port 274. The oxidant-exhaust gas mixture 280 reverses direction at the gap 340, and enters the second space 286 moving toward the head end portion 166. By introducing the oxidant 68 downstream of the bell mouth 350, any leakage of oxidant 68 is less likely to enter the compressed exhaust gas 170 contained by the casing 270. As discussed above, it may be beneficial to help block the oxidant 68 from entering the compressed exhaust gas 170, such that oxygen-free exhaust gas may be extracted from the combustor section 154. In other embodiments, the oxidant port 274 may be located closer to the bell mouth 350 and the plurality of impingement cooling orifices 284 shown in FIG. 5 may be used to transfer the oxidant-exhaust gas mixture 280 from the first space 272 to the second space 286. As discussed above, either premix fuel nozzles or diffusion fuel nozzles may be used in the illustrated combustor section 154. In addition, the combustor section 154 may be used for stoichiometric combustion, as discussed above. In addition, the oxidant conduit 276 may segregate the oxidant 68 from the compressed exhaust gas 170 outside of the third wall 268.
In addition, the compressed exhaust gas 170 within the combustion casing 270 may be extracted through the exhaust gas extraction port 312 to be used as the exhaust gas 42 in the exhaust gas supply system 78, as described in detail above. Specifically, the exhaust gas extraction port 312 is disposed upstream of the bell mouth 350 where the exhaust gas 170 enters the first space 272 and mixes with the oxidant 68. By disposing the exhaust gas extraction port 312 upstream of where the oxidant 68 is added, the extracted exhaust gas 42 is kept free of oxidant 68, which may be important in certain applications, such as the oil/gas extraction system 16 or the EOR system 18.

FIG. 9 is a cross-sectional view of the first, second, and third walls 264, 266, and 268 shown in FIG. 7 taken within the line 9-9. As shown in FIG. 9, a plurality of turbulators 360 may be formed in the first wall 264. In certain embodiments, the plurality of turbulators 360 may be formed by creating grooves in the first wall 264. Each of the plurality of turbulators 360 may create a vortex 362, or swirling flow, of the oxidant-exhaust gas mixture 280 flowing through the second space 286. In addition, the plurality of turbulators 360 may increase the surface area of the first wall 264 available for heat transfer. Thus, the plurality of turbulators 360 may improve the heat transfer across the first wall 264. In other words, the plurality of turbulators 360 may enable the oxidant-exhaust gas mixture 280 to provide improved cooling of the first wall 264. In addition, the plurality of turbulators 360 may help improve mixing of the oxidant-exhaust gas mixture 280 along the second path 290. In other embodiments, other flow enhancement devices may be disposed along any of the first, second, or third walls, 264, 266, or 268 to improve the cooling provided by the oxidant-exhaust gas mixture 280 and/or the mixing of the oxidant-exhaust gas mixture 280.

As described above, certain embodiments of the combustor 160 may include the first wall 264 disposed about the combustion chamber 262, the second wall 266 disposed about the first wall 264, and the third wall 268 disposed about the second wall 266. The third wall 268 may combine the compressed exhaust gas 170 with the oxidant 68 to generate the oxidant-exhaust gas mixture 280. In addition the combustion chamber 262 may be configured to combust the mixture of the fuel 70,
the oxidant 68, and the compressed exhaust gas 170. In further embodiments, at least one of the first, second, and third walls 264, 266, and 268 may pass the compressed exhaust gas 170. By using the third wall 268 in the combustor 160, the oxidant-exhaust gas mixture 280 may be used to cool various components of the combustor 160, thereby improving the longevity of the components. For example, the oxidant-exhaust gas mixture 280 may be used to cool surfaces of the first wall 264, such as the combustion liner 296 and the transition piece 298. In addition, the third wall 268 provides more length, or a longer path, for mixing of the oxidant-exhaust gas mixture 280, while also isolating the oxidant 68 from the extracted exhaust gas 42. In addition, reversing the direction of the oxidant-exhaust gas mixture 280 using the third wall 268 may enhance mixing. Further, the arrangement of the exhaust gas ports 278 and oxidant port 274 coupled to the third wall 268 are used to mix the oxidant 68 and the exhaust gas 170 is different from other combustors. Normally, the oxidant 68 and exhaust gas 170 would not be mixed together in this location in other combustors.

ADDITIONAL DESCRIPTION

[0079] The present embodiments provide systems and methods for turbine combustors of gas turbine engines. It should be noted that any one or a combination of the features described above may be utilized in any suitable combination. Indeed, all permutations of such combinations are presently contemplated. By way of example, the following clauses are offered as further description of the present disclosure:

[0080] Embodiment 1. A system, comprising: a turbine combustor, comprising:
a first wall disposed about a combustion chamber; a second wall disposed about the first wall; and a third wall disposed about the second wall, wherein the third wall is configured to combine an exhaust gas with an oxidant, and the combustion chamber is configured to combust a mixture of a fuel, the oxidant, and the exhaust gas.

[0081] Embodiment 2. The system of embodiment 1, wherein the third wall comprises at least one oxidant port and at least one exhaust gas port.
Embodiment 3. The system defined in any preceding embodiment, wherein the at least one oxidant port is disposed upstream from the at least one exhaust gas port.

Embodiment 4. The system defined in any preceding embodiment, wherein the at least one oxidant port is disposed downstream from the at least one exhaust gas port.

Embodiment 5. The system defined in any preceding embodiment, wherein the turbine combustor is configured to receive the oxidant at a first pressure into the at least one oxidant port and the exhaust gas at a second pressure into the at least one exhaust gas port, wherein the first pressure is less than the second pressure.

Embodiment 6. The system defined in any preceding embodiment, comprising at least one oxidant conduit extending through a casing of the combustor to the at least one oxidant port, wherein the at least one oxidant conduit is configured to segregate the oxidant from the exhaust gas outside of the third wall.

Embodiment 7. The system defined in any preceding embodiment, wherein the at least one exhaust port comprises a plurality of exhaust ports, a bell mouth, or any combination thereof.

Embodiment 8. The system defined in any preceding embodiment, wherein the turbine combustor comprises a first space between the second and third walls and a second space between the first and second walls, and the turbine combustor comprises a flow path having a first path through the first space and a second path through the second space.

Embodiment 9. The system defined in any preceding embodiment, wherein the flow path reverses directions from the first path to the second path.

Embodiment 10. The system defined in any preceding embodiment, wherein the turbine combustor comprises a plurality of turbulators disposed along the flow path.
Embodiment 11. The system defined in any preceding embodiment, wherein the second wall comprises a plurality of impingement cooling orifices.

Embodiment 12. The system defined in any preceding embodiment, wherein the first wall comprises at least one of a combustion liner or a transition piece, the second wall comprises at least one of a flow sleeve or an impingement sleeve, and the third wall comprises an outer sleeve.

Embodiment 13. The system defined in any preceding embodiment, comprising a first hula seal configured to couple the combustion liner and the transition piece, a second hula seal configured to couple the flow sleeve and the impingement sleeve, and a third hula seal configured to couple first and second portions of the outer sleeve, wherein the first portion of the outer sleeve is disposed about the flow sleeve, and the second portion of the outer sleeve is disposed about the impingement sleeve.

Embodiment 14. The system defined in any preceding embodiment, comprising a bypass tube passing through the first, second, and third walls, wherein the bypass tube is configured to transfer the exhaust gas directly to the combustion chamber.

Embodiment 15. The system defined in any preceding embodiment, comprising a gas turbine engine having the turbine combustor, a turbine driven by combustion products from the turbine combustor, and an exhaust gas compressor driven by the turbine, wherein the exhaust gas compressor is configured to compress and route the exhaust gas to the turbine combustor.

Embodiment 16. The system defined in any preceding embodiment, comprising an exhaust gas extraction system coupled to the gas turbine engine, and a hydrocarbon production system coupled to the exhaust gas extraction system.

Embodiment 17. The system defined in any preceding embodiment, wherein the gas turbine engine is a stoichiometric exhaust gas recirculation (SEGR) gas turbine engine.
Embodiment 18. A system, comprising: a triple-wall turbine combustor, comprising: a first wall disposed about a combustion chamber; a second wall disposed about the first wall; and a third wall disposed about the second wall, wherein at least one of the first, second, and third walls is configured to pass an exhaust gas, and the combustion chamber is configured to combust a mixture of a fuel, an oxidant, and the exhaust gas.

Embodiment 19. The system defined in any preceding embodiment, comprising a stoichiometric exhaust gas recirculation (SEGR) gas turbine engine having the triple-wall turbine combustor, a turbine driven by combustion products from the triple-wall turbine combustor, and an exhaust gas compressor driven by the turbine, wherein the exhaust gas compressor is configured to compress and route the exhaust gas to the triple-wall turbine combustor.

Embodiment 20. The system defined in any preceding embodiment, comprising an exhaust gas extraction system coupled to the SEGR gas turbine engine, and a hydrocarbon production system coupled to the exhaust gas extraction system.

Embodiment 21. A method, comprising: flowing an exhaust gas and an oxidant along a flow path of a multi-wall turbine combustor between a first wall surrounding a combustion chamber, a second wall surrounding the first wall, and a third wall surrounding the second wall; and combusting a mixture of a fuel, the oxidant, and the exhaust gas within the combustion chamber.

Embodiment 22. The method or system defined in any preceding embodiment, comprising supplying the oxidant and the exhaust gas independently into the third wall of the multi-wall turbine combustor.

Embodiment 23. The method or system defined in any preceding embodiment, comprising flowing the exhaust gas and the oxidant in a first direction between the second and third walls, and reversing flow of the exhaust gas and the oxidant to flow in a second direction between the first and second walls.
Embodiment 24. The method or system defined in any preceding embodiment, comprising routing flow of the exhaust gas and the oxidant through a plurality of impingement cooling orifices in the second wall to impingement cool the first wall.

Embodiment 25. The method or system defined in any preceding embodiment, comprising mixing flow of the exhaust gas and the oxidant with a plurality of turbulators along the flow path.

Embodiment 26. The method or system defined in any preceding embodiment, wherein combusting comprises stoichiometrically combusting the mixture.

Embodiment 27. The method or system defined in any preceding embodiment, comprising extracting a portion of the exhaust gas, and routing the portion of exhaust gas to a hydrocarbon production system.

Embodiment 28. The method or system defined in any preceding embodiment, wherein the turbine combustor is configured to combust a mixture of a fuel and an oxidant with an equivalence ratio of approximately 0.95 to approximately 1.05.

This written description uses examples to disclose the invention, including the best mode, and also to enable any person skilled in the art to practice the invention, including making and using any devices or systems and performing any incorporated methods. The patentable scope of the invention is defined by the claims, and may include other examples that occur to those skilled in the art. Such other examples are intended to be within the scope of the claims if they have structural elements that do not differ from the literal language of the claims, or if they include equivalent structural elements with insubstantial differences from the literal language of the claims.
CLAIMS:

1. A system, comprising:
   a turbine combustor, comprising:
      a first wall disposed about a combustion chamber;
      a second wall disposed about the first wall; and
      a third wall disposed about the second wall, wherein the third wall is
      configured to combine an exhaust gas with an oxidant, and the combustion chamber is
      configured to combust a mixture of a fuel, the oxidant, and the exhaust gas.

2. The system of claim 1, wherein the third wall comprises at least one oxidant
   port and at least one exhaust gas port.

3. The system of claim 2, wherein the at least one oxidant port is disposed
   upstream from the at least one exhaust gas port.

4. The system of claim 2, wherein the at least one oxidant port is disposed
   downstream from the at least one exhaust gas port.

5. The system of claim 2, wherein the turbine combustor is configured to receive
   the oxidant at a first pressure into the at least one oxidant port and the exhaust gas at a
   second pressure into the at least one exhaust gas port, wherein the first pressure is less
   than the second pressure.

6. The system of claim 2, comprising at least one oxidant conduit extending
   through a casing of the combustor to the at least one oxidant port, wherein the at least
   one oxidant conduit is configured to segregate the oxidant from the exhaust gas
   outside of the third wall.

7. The system of claim 2, wherein the at least one exhaust port comprises a
   plurality of exhaust ports, a bell mouth, or any combination thereof.
8. The system of claim 1, wherein the turbine combustor comprises a first space between the second and third walls and a second space between the first and second walls, and the turbine combustor comprises a flow path having a first path through the first space and a second path through the second space.

9. The system of claim 8, wherein the flow path reverses directions from the first path to the second path.

10. The system of claim 8, wherein the turbine combustor comprises a plurality of turbulators disposed along the flow path.

11. The system of claim 8, wherein the second wall comprises a plurality of impingement cooling orifices.

12. The system of claim 1, wherein the first wall comprises at least one of a combustion liner or a transition piece, the second wall comprises at least one of a flow sleeve or an impingement sleeve, and the third wall comprises an outer sleeve.

13. The system of claim 12, comprising a first hula seal configured to couple the combustion liner and the transition piece, a second hula seal configured to couple the flow sleeve and the impingement sleeve, and a third hula seal configured to couple first and second portions of the outer sleeve, wherein the first portion of the outer sleeve is disposed about the flow sleeve, and the second portion of the outer sleeve is disposed about the impingement sleeve.

14. The system of claim 1, comprising a bypass tube passing through the first, second, and third walls, wherein the bypass tube is configured to transfer the exhaust gas directly to the combustion chamber.

15. The system of claim 1, comprising a gas turbine engine having the turbine combustor, a turbine driven by combustion products from the turbine combustor, and
an exhaust gas compressor driven by the turbine, wherein the exhaust gas compressor
is configured to compress and route the exhaust gas to the turbine combustor.

16. The system of claim 15, comprising an exhaust gas extraction system coupled
to the gas turbine engine, and a hydrocarbon production system coupled to the exhaust
gas extraction system.

17. The system of claim 15, wherein the gas turbine engine is a stoichiometric
exhaust gas recirculation (SEGR) gas turbine engine.

18. A system, comprising:
   a triple-wall turbine combustor, comprising:
   a first wall disposed about a combustion chamber;
   a second wall disposed about the first wall; and
   a third wall disposed about the second wall, wherein at least one of the
   first, second, and third walls is configured to pass an exhaust gas, and the combustion
   chamber is configured to combust a mixture of a fuel, an oxidant, and the exhaust gas.

19. The system of claim 18, comprising a stoichiometric exhaust gas recirculation
(SEGR) gas turbine engine having the triple-wall turbine combustor, a turbine driven
by combustion products from the triple-wall turbine combustor, and an exhaust gas
compressor driven by the turbine, wherein the exhaust gas compressor is configured
to compress and route the exhaust gas to the triple-wall turbine combustor.

20. The system of claim 19, comprising an exhaust gas extraction system coupled
to the SEGR gas turbine engine, and a hydrocarbon production system coupled to the
exhaust gas extraction system.
21. A method, comprising:
   flowing an exhaust gas and an oxidant along a flow path of a multi-wall
turbine combustor between a first wall surrounding a combustion chamber, a second
wall surrounding the first wall, and a third wall surrounding the second wall; and
   combusting a mixture of a fuel, the oxidant, and the exhaust gas within the
combustion chamber.

22. The method of claim 21, comprising supplying the oxidant and the exhaust gas
independently into the third wall of the multi-wall turbine combustor.

23. The method of claim 21, comprising flowing the exhaust gas and the oxidant
in a first direction between the second and third walls, and reversing flow of the
exhaust gas and the oxidant to flow in a second direction between the first and second
walls.

24. The method of claim 21, comprising routing flow of the exhaust gas and the
oxidant through a plurality of impingement cooling orifices in the second wall to
impingement cool the first wall.

25. The method of claim 21, comprising mixing flow of the exhaust gas and the
oxidant with a plurality of turbulators along the flow path.

26. The method of claim 21, wherein combusting comprises stoichiometrically
combusting the mixture.

27. The method of claim 21, comprising extracting a portion of the exhaust gas,
and routing the portion of exhaust gas to a hydrocarbon production system.
INITIATE STARTUP MODE OF SEGR GAS TURBINE SYSTEM

SUPPLY COMPRESSED OXIDANT TO COMBUSTOR(S) AND FUEL NOZZLE(S)

SUPPLY FUEL TO COMBUSTOR(S) AND FUEL NOZZLE(S)

SUPPLY EXHAUST GAS (AS AVAILABLE) TO COMBUSTOR(S) AND FUEL NOZZLE(S)

COMBUST MIXTURE IN COMBUSTOR(S) TO PRODUCE HOT COMBUSTION GAS

DRIVE TURBINE WITH HOT COMBUSTION GAS

TREAT EXHAUST GAS FROM TURBINE

RECIRCULATE EXHAUST GAS TO COMPRESSOR OF SEGR GAS TURBINE SYSTEM

COMPRESS EXHAUST GAS IN COMPRESSOR

TRANSITION TO STEADY STATE MODE

EXTRACT EXHAUST GAS

SUPPLY EXHAUST GAS TO OIL/GAS PRODUCTION SYSTEM

INJECT EXHAUST GAS INTO EARTH FOR ENHANCED OIL RECOVERY (EOR)
