MOBILITY IN A MULTI-ACCESS COMMUNICATION NETWORKField of the Invention

[0001] The present invention relates to communications, and in particular
5 to allowing a mobile terminal to communicate with other communication
devices via disparate access networks.

Background of the Invention

[0002] Expansion of packet-based networks, such as the Internet, is
10 extending into mobile environments. Accordingly, mobile terminals equipped
with wireless communication capability can now establish communication
sessions with other communication devices in part over wireless
communication channels. Unfortunately, there are numerous wireless
communication networks using different communication technologies and
15 protocols. In an effort to increase functionality, these mobile terminals may be
equipped to communicate with different types of networks using the same or
different access technologies. With such capabilities, there is a need for an
efficient technique to allow the mobile terminals to communicate with the other
communication devices over different access networks . There is a further
20 need for an effective technique to transition through sequential connections
over these different access networks as the user element moves from one
access network to another.

Summary of the Invention

25 [0003] The present invention provides a terminal with the capability of
establishing multiple communication sessions with a public network proxy
through different access networks. The terminal can actively communicate
with the public network proxy to control which of the multiple communication
paths are active, as well as control the transition from actively using one
30 communication path to using another. The public network proxy will facilitate
communications between the terminal and any number of other
communication devices to facilitate data or voice sessions. In one
embodiment, the communication sessions are reserved tunneling sessions,
and the terminal cooperates with the public network proxy to effectively

52829-28

2

control how many tunneling sessions are established, how many tunneling sessions are active at any given time, and the transition from one tunneling session to another for active communications. Each of the communication or tunneling sessions may be established over different access networks using different communication technologies and protocols.

[0003a] According to one aspect of the present invention, there is provided a method for facilitating packet communications from a terminal to a network proxy comprising: a) establishing a plurality of communication sessions via a plurality of access networks with the network proxy, which facilitates communications between the terminal and at least one communication device; b) selecting one of the plurality of communication sessions to be a first active communication session, wherein the selecting is based on one or more factors related to the access networks pertaining to cost or performance; c) identifying the first active communication session to the network proxy; and d) transferring packets to or from the network proxy using the first active communication session to effect communications with the at least one communication device.

[0003b] According to another aspect of the present invention, there is provided a terminal for facilitating packet communications over a plurality of access networks comprising: communication circuitry that facilitates communications with the plurality of access networks; and a control system associated with the communication circuitry, wherein the control system is configured to: establish a plurality of communication sessions via the plurality of access networks with a network proxy, which facilitates communications between the terminal and at least one communication device; select one of the plurality of communication sessions to be a first active communication session, wherein the selection is based on one or more factors related to the access networks pertaining to cost or performance; identify the first active communication session to the network proxy; and transfer packets to or from the network proxy using the first active communication session to effect communications with the at least one communication device.

52829-28

2a

[0003c] According to still another aspect of the present invention, there is provided a method for facilitating packet communications between a terminal and at least one communication device via a network proxy comprising: a) establishing a plurality of communication sessions via a plurality of access networks with the terminal; b) receiving selection indicia based on one or more factors related to the access networks pertaining to cost or performance from the terminal identifying one of the plurality of communication sessions to be a first active communication session; c) transferring packets to or from the terminal using the first active communication session to effect communications with the terminal; and d) communicating with the at least one communication device on behalf of the terminal.

[0003d] According to yet another aspect of the present invention, there is provided a network proxy for facilitating packet communications between a terminal and at least one communication device comprising: a) communication circuitry that facilitates communications with the plurality of access networks; and b) a control system associated with the communication circuitry wherein the control system: i) establishes a plurality of communication sessions via the plurality of access networks with the terminal, ii) receives selection indicia based on one or more factors related to the access networks pertaining to cost or performance from the terminal identifying one of the plurality of communication sessions to be a first active communication session; iii) transfers packets to or from the terminal using the first active communication session to effect communications with the terminal; and iv) communicates with the at least one communication device on behalf of the terminal.

[0003e] According to a further aspect of the present invention, there is provided one or more computer hardware storage media having stored thereon executable instructions which, when executed by one or more processors, cause the one or more processors to: establish a plurality of communication sessions via a plurality of access networks, with a network proxy, which facilitates communications between a terminal and at least one communication device; select one of the plurality of communication sessions to be a first active communication session, wherein the selection is based on one or more factors relating to the access network pertaining to

52829-28

2b

cost or performance; identify the first active communication session to the network proxy; and transfer packets to or from the network proxy using the first active communication session to effect communications with the at least one communication device.

addressed herein. It should be understood that these concepts and applications fall within the scope of the disclosure and the accompanying claims.

[0011] The present invention allows a mobile terminal to effectively control the paths through which it will communicate with a public network proxy,

which facilitates communications with any number of communication devices for data or voice applications. The different communication paths to the public network proxy may be supported by different access networks using different communication technologies and protocols. In operation, the mobile terminal
5 will take the necessary steps to establish communication paths and determine which of these communication paths will be active and facilitate the transmission and reception of packets to and from the public network proxy. A decision between two available communication paths may be based on cost or performance characteristics. Based on instructions from the mobile
10 terminal, the public network proxy will take the necessary steps to facilitate communications between the appropriate communication devices and the mobile terminal over the active communication path or paths, as well as facilitate handoffs from one access network to another. The handoffs will preferably be initiated by the mobile terminal via instructions sent to the public
15 network proxy. Further, multiple communication paths may be active at the same time, wherein duplicate packets are simultaneously sent over different communication paths. Alternatively, the multiple communication paths may be used to increase transfer rates. In one embodiment, the communication paths are tunneling sessions established between the mobile terminal and the
20 public network proxy via the various access networks using any number of tunneling protocols, such as through one or more Internet Protocol (IP) Security (SEC) connections or virtual private networks (VPNs).

[0012] To the correspondent communication devices, the mobile terminal will be associated with a public IP address, which is supported by the public
25 network proxy. As such, packets sent to the mobile terminal will be sent to the public network proxy using the public IP address of the mobile terminal. Depending on the access network through which the mobile terminal can be reached by the public network proxy, different temporary IP addresses will be assigned to the mobile terminal for the various access networks. The public
30 network proxy will use the appropriate temporary IP address for forwarding the packets received from the communication devices on to the mobile terminal within the confines of the tunneling protocols. In return, the mobile terminal will encapsulate packets intended for the communication devices using the appropriate tunneling protocols, which effects delivery of the

52829-28

4

packets initially to the public network proxy, which will extract the original packets and forward them as necessary to the communication devices.

Again, the packets transferred between the mobile terminal and the communication devices through the public network proxy may include voice or data, the latter of which may include virtually any type of information, audio, or video.

[0013] With reference to Figure 1, a communication environment 10 according to the present invention is illustrated, wherein the mobile terminal 14 is capable of communicating with numerous communication devices 16 with the aid of the public network proxy 12. The mobile terminal 14 may be any portable device capable of facilitating communications via multiple access networks. Examples include personal computers, personal digital assistants, mobile telephones, or any other device benefiting from communicating with remote communication devices. In general, the public network proxy 12 and the communication devices 16 are directly or indirectly coupled to a packet network 18, which is further coupled to numerous access networks 20. These access networks 20 may support various wired or wireless communications with the mobile terminal 14, depending on the communication capabilities of the mobile terminal 14. As illustrated for exemplary purposes only, there are four access networks 20 operatively coupled to the packet network 18, wherein each access network 20 supports one of the following communication technologies: local wireless (BluetoothTM), wireless local area network (WLAN), cellular, and traditional wired Ethernet. Although only one of each type of access network 20 is illustrated, there may be multiple access network 20 providing disparate or overlapping coverage. For each of the access networks 20, an access point 22 that is capable of providing the actual wired or wireless communication link to the mobile terminal 14 is provided. For the Bluetooth and WLAN access networks 20, the access points 22 may be a simple Bluetooth or WLAN modem, which is capable of providing bi-directional wireless communications with the mobile terminal 14. The access point or points for a cellular access network 20 is generally a cellular network of base stations 24 operating in traditional fashion. Further, the Ethernet-based access network 20 will have an access point 22 capable of supporting a wired Ethernet connection.

[0014] Regardless of the communication technology incorporated by the access network 20 and associated access point 22, the mobile terminal 14 is capable of establishing communications with the access network 20 via the access points 22 (or base stations 24), and ultimately with the public network proxy 12 via the packet network 18 using any available communication protocol, and preferably a tunneling protocol to effectively define a communication path between the mobile terminal 14 and the public network proxy 12.

[0015] In operation, the mobile terminal 14 is capable of establishing tunneling sessions through multiple ones of the access networks 20 as communication capability permits. As such, at any given time, the mobile terminal 14 may have multiple tunneling sessions through which communications with the public network proxy 12 can be supported. With reference now to Figure 2, a flow diagram is provided to illustrate how communications between the mobile terminal 14 and the public network proxy 12 are established and controlled predominantly by the mobile terminal 14.

[0016] Initially, the mobile terminal 14 will establish layer 2 and 3 connectivity with one or more available access networks 20 via the respective access points 22 (which include the base stations 24) (step 100). Although the flow diagram of Figure 2 focuses on using two connections, the invention is applicable for any number of connections. Further, each connection may be fully separate in setup and function with respect to other connections. The access networks 20 will recognize the connectivity and the packet capability of the mobile terminal 14 and provide temporary IP addresses, designated IP_1 and IP_2 , for the WLAN and cellular access networks 20, respectively, and send the temporary IP addresses IP_1 and IP_2 to the mobile terminal 14. The mobile terminal 14 will receive the temporary IP addresses IP_1 and IP_2 from the respective access networks 20 (step 102), and establish tunneling sessions with the public network proxy 12 through each access network 20 using the respective temporary IP addresses (step 104). Notably, the communication devices 16 will use the primary address for the mobile terminal 14, IP_P , to send packets toward the mobile terminal 14, wherein the packets will actually be received by the public network proxy 12 on behalf of the mobile terminal 14.

[0017] At this point, the mobile terminal 14 has established two tunneling sessions, referenced as 26 and 28 in Figure 1. In one embodiment, the mobile terminal 14 will select a first tunneling session to be an active tunneling session (step 106) and notify the public network proxy 12 of the selection of the first tunneling session as the primary tunneling session (step 108). Such selection may be accomplished in many ways. For example, the mobile terminal 14 may establish multiple IP Security (IPSec) tunnels using the same credentials. The public network proxy 12 will recognize it as the same client. Then, by choosing to send the outbound packets over one tunnel, it will be defined as the active tunnel. If the mobile terminal 14 uses both tunnels to send packets, then the tunnels are in a load-sharing mode for increased bandwidth. If the mobile terminal 14 uses both tunnels to send identical packets, then the mobile terminal 14 is using the two channels for improved reliability or to begin the process of transitioning from one tunnel being active to the other. Although the second tunneling session is available, the mobile terminal 14 and the public network proxy 12 will operate to send and receive packets via the first tunneling session 26 using the first temporary IP address, IP_1 (step 110). In the background, the public network proxy 12 will forward packets received from the mobile terminal 14 to the appropriate communication device 16, as well as receive packets from the communication devices 16 and forward them to the mobile terminal 14 using the first temporary IP address IP_1 within the first tunneling session 26.

[0018] At some point, assume that the mobile terminal 14 detects a need to transition to the second tunneling session 28 from the first tunneling session 26 due to observed communication errors, transmission rates, quality of service issues, or desired service plans (step 112). Accordingly, the mobile terminal 14 will notify the public network proxy 12 of the need to transition to the second tunneling session 28 through either of the first or second tunneling sessions 26, 28 (step 114). At this point, the public network proxy 12 may begin a transition phase, wherein the mobile terminal 14 and public network proxy 12 send and receive packets via the first and second tunneling sessions 26, 28 using the respective temporary IP addresses, IP_1 and IP_2 (step 116). Such a transition is beneficial to prevent a break in voice or streaming media services. During this transition or handoff, duplicate packets may be sent

over the first and second tunneling sessions 26, 28, and the receiving entity, either the public network proxy 12 or the mobile terminal 14, may simply monitor packet header information, such as sequence numbering, to determine whether a packet is a duplicate packet of one which has already
5 been received.

[0019] At some point during the transition period, the mobile terminal 14 will detect the desirability to stop using or the inability to use the first tunneling session 26 (step 118). The mobile terminal 14 may directly or indirectly notify the public network proxy 12 of the permanent selection of the second
10 tunneling session 28 (step 120), by sending a signal or by no longer using or being able to use the connection. Thus, notification may be simply a recognition that the connection is no longer available or in use. The packets are then sent and received only via the second tunneling session 28 using the second temporary IP address, IP₂ (step 122).

15 [0020] In addition to selecting a first tunneling session 26 and transitioning as necessary to a second tunneling session 28 during handoffs between one access network 20 and another, the mobile terminal 14 can control the use of the multiple tunneling sessions in any desired fashion, wherein duplicate packets may be sent over the multiple tunneling sessions to improve
20 communication resiliency and increase quality of service, as well as have different packets sent over the different tunneling sessions to increase effective transfer rates between the public network proxy 12 and the mobile terminal 14 in either direction. The mobile terminal 14 will effectively control the public network proxy 12 to determine when and how packets are sent and
25 when handoffs from one tunneling session to another occur. Further, the mobile terminal 14 can decide how many tunneling sessions should be established, and how many of those established tunneling sessions are active. Accordingly, multiple tunneling sessions may be available at any given time, but only one or more of those tunneling sessions may be in active use.
30 An active management system can be used to establish multiple tunnels independently and manage them in a desired fashion. As an example, the Session Initiation Protocol (SIP) may be used to enable a single session to have multiple streams. These streams can be added and removed and have attributes such as Codec, frame size, and the like. Any tunnel or connection

could be used to carry the SIP messages, and the stream definitions could be modified to define which are active and whether they are in redundant or bandwidth augmentation mode.

[0021] Turning now to Figure 3, a block diagram of a public network proxy 12 is illustrated. The public network proxy 12 will preferably include a control system 32, which may include a central processing unit (CPU), having sufficient memory 34 to store the software 36 necessary for operation as described above. The control system 32 is also associated with one or more packet interfaces 38 to facilitate communications with the various communication devices 16 and the access networks 20.

[0022] Those skilled in the art will recognize the numerous forms the mobile terminal 14 may take. The basic communication architecture of the mobile terminal 14 is represented in Figure 4 and includes a receiver front end 40, a radio frequency transmitter section 42, an antenna 44, a duplexer or switch 46, a baseband processor 48, a control system 50, a frequency synthesizer 52, and an interface 54. The receiver front end 40 receives information bearing radio frequency signals from one or more remote transmitters provided by a base station. A low noise amplifier 56 amplifies the signal. A filter circuit 58 minimizes broadband interference in the received signal, while downconversion and digitization circuitry 60 downconverts the filtered, received signal to an intermediate or baseband frequency signal, which is then digitized into one or more digital streams. The receiver front end 40 typically uses one or more mixing frequencies generated by the frequency synthesizer 52. The baseband processor 48 processes the digitized received signal to extract the information or data bits conveyed in the received signal. This processing typically comprises demodulation, decoding, and error correction operations. As such, the baseband processor 48 is generally implemented in one or more digital signal processors (DSPs).

[0023] On the transmit side, the baseband processor 48 receives digitized data, which may represent voice, data, or control information, from the control system 50, which it encodes for transmission. The encoded data is output to the transmitter 42, where it is used by a modulator 62 to modulate a carrier signal that is at a desired transmit frequency. Power amplifier circuitry 64 amplifies the modulated carrier signal to a level appropriate for transmission,

and delivers the amplified and modulated carrier signal to the antenna 44 through the duplexer or switch 46.

[0024] As noted above, the mobile terminal 14 must be able to communicate with multiple ones of the access networks 20 via the various access points 22, which are generally defined to include the network of base stations 24. Accordingly, the receiver front end 40, baseband processor 48, and radio frequency transmitter section 42 cooperate to provide one or more of the following interfaces: Bluetooth (or other local wireless interface), WLAN, or cellular. Further, an Ethernet interface 66 may be provided for a more traditional wired connection to a corresponding access network 20. Wireless communication capability may be implemented using redundant circuitry, or by configuring common circuitry to operate in different modes. The configuration of the mobile terminal 14 will be dictated by economics and designer choice. The mobile terminal 14 is configured such that the proper mode of operation is selected by the control system 50, which will also implement the necessary protocols and packet processing for the various communication technologies. As noted above, the above communication circuitry is preferably configured to effectively communicate in different modes at the same time. Further, a user may interact with the mobile terminal 14 via the interface 54, which may include interface circuitry associated with a microphone, a speaker, a keypad, and a display.

[0025] Those skilled in the art will recognize improvements and modifications to the preferred embodiments of the present invention. All such improvements and modifications are considered within the scope of the concepts disclosed herein and the claims that follow.

52829-28

10

CLAIMS:

1. A method for facilitating packet communications from a terminal to a network proxy comprising:

5 a) establishing a plurality of communication sessions via a plurality of access networks with the network proxy, which facilitates communications between the terminal and at least one communication device;

b) selecting one of the plurality of communication sessions to be a first active communication session, wherein the selecting is based on one or more factors related to the access networks pertaining to cost or performance;

10 c) identifying the first active communication session to the network proxy; and

d) transferring packets to or from the network proxy using the first active communication session to effect communications with the at least one communication device.

15 2. The method of claim 1 further comprising:

e) selecting at least a second one of the plurality of communication sessions to be a second active communication session wherein there are at least first and second active communication sessions; and

20 f) transferring packets to or from the network proxy using the first and second active communication sessions to effect the communications with the at least one communication device.

3. The method of claim 1, wherein the one or more factors related to the access networks comprise communication errors.

25 4. The method of claim 1, wherein the one or more factors related to the access networks comprise transmission rate.

52829-28

11

5. The method of claim 1, wherein the one or more factors related to the access networks comprise quality of service.

6. The method of claim 1, wherein the one or more factors related to the access networks comprises one or more rate plans associated with the access
5 networks.

7. The method of claim 2 wherein the packets transferred using the first active communication session carry information different than carried in the packets transferred using the second active communication session.

8. The method of claim 2 wherein the packets are duplicated and sent
10 over both the first and second active communication sessions.

9. The method of claim 1 further comprising:

e) determining a need to switch from the first active communication session;

f) selecting at least a second one of the plurality of communication
15 sessions to be a second active communication session;

g) providing indicia indicative of the need to switch from the first active communication session to the second active communication session; and

h) transferring packets to or from the network proxy using only the second active communication session to effect the communications with the at least
20 one communication device.

10. The method of claim 9 further comprising transferring the packets to or from the network proxy using the first and second active communication sessions to effect the communications with the at least one communication device prior to using only the second active communication session.

52829-28

12

11. The method of claim 10 further comprising sending second indicia instructing the network proxy to stop using the first active communication session.

12. The method of claim 1 further comprising receiving temporary IP addresses from the respective access networks and using the temporary IP
5 addresses to establish the plurality of communication sessions, wherein a public IP address associated with the terminal is supported by the network proxy.

13. The method of claim 1 wherein the communication sessions are tunneling sessions with the network proxy.

14. The method of claim 1 wherein communications with the plurality of
10 access networks are based on disparate communication technologies.

15. A terminal for facilitating packet communications over a plurality of access networks comprising:

communication circuitry that facilitates communications with the plurality of access networks; and

15 a control system associated with the communication circuitry, wherein the control system is configured to:

establish a plurality of communication sessions via the plurality of access networks with a network proxy, which facilitates communications between the terminal and at least one communication device;

20 select one of the plurality of communication sessions to be a first active communication session, wherein the selection is based on one or more factors related to the access networks pertaining to cost or performance;

identify the first active communication session to the network proxy; and

52829-28

13

transfer packets to or from the network proxy using the first active communication session to effect communications with the at least one communication device.

16. The terminal of claim 15 wherein the control system is further adapted to:

selects at least a second one of the plurality of communication sessions to be a second active communication session wherein there are at least first and second active communication sessions; and

transfers packets to or from the network proxy using the first and second active communication sessions to effect the communications with the at least one communication device.

17. The terminal of claim 15, wherein the one or more factors related to the access networks comprises communication errors.

18. The terminal of claim 15, wherein the one or more factors related to the access networks comprises transmission rate.

19. The terminal of claim 15, wherein the one or more factors related to the access networks comprises quality of service.

20. The terminal of claim 15, wherein the one or more factors related to the access networks comprises one or more rate plans associated with the access networks.

21. The terminal of claim 16 wherein the packets transferred using the first active communication session carry information different than carried in the packets transferred using the second active communication session.

22. The terminal of claim 16 wherein the packets are duplicated and sent over both the first and second active communication sessions.

52829-28

14

23. The terminal of claim 15 wherein the control system further:

v) determine a need to switch from the first active communication session;

5 vi) select at least a second one of the plurality of communication sessions to be a second active communication session;

vii) send indicia indicative of the need to switch from the first active communication session to the second active communication session; and

10 viii) transfer packets to or from the network proxy using only the second active communication session to effect the communications with the at least one communication device.

24. The terminal of claim 23 wherein the control system further transfers the packets to or from the network proxy using the first and second active communication sessions to effect the communications with the at least one communication device prior to using only the second active communication session.

25. The terminal of claim 24 wherein the control system further sends second indicia instructing the network proxy to stop using the first active communication session.

26. The terminal of claim 15 wherein the control system further receives temporary IP addresses from the respective access networks and uses the temporary IP addresses to establish the plurality of communication sessions, wherein a public IP address associated with the terminal is supported by the network proxy.

27. The terminal of claim 15 wherein the communication sessions are tunneling sessions with the network proxy.

28. The terminal of claim 15 wherein communications with the plurality of access networks are based on disparate communication technologies.

52829-28

15

29. A method for facilitating packet communications between a terminal and at least one communication device via a network proxy comprising:

a) establishing a plurality of communication sessions via a plurality of access networks with the terminal;

5 b) receiving selection indicia based on one or more factors related to the access networks pertaining to cost or performance from the terminal identifying one of the plurality of communication sessions to be a first active communication session;

10 c) transferring packets to or from the terminal using the first active communication session to effect communications with the terminal; and

d) communicating with the at least one communication device on behalf of the terminal.

30. The method of claim 29 further comprising:

15 e) receiving second selection indicia from the terminal identifying at least a second one of the plurality of communication sessions to be an active communication session wherein there are at least first and second active communication sessions; and

20 f) transferring packets to or from the terminal using the first and second active communication sessions to effect communications between the terminal and the at least one communication device.

31. The method of claim 30 wherein the packets transferred using the first active communication session carry information different than carried in the packets transferred using the second active communication session.

25 32. The method of claim 30 wherein the packets are duplicated and sent over both the first and second active communication sessions.

52829-28

16

33. The method of claim 29 further comprising:

e) receiving switch indicia from the terminal indicating a need to switch from the first active communication session;

5 f) receiving first selection indicia from the terminal identifying at least a second one of the plurality of communication sessions to be a second active communication session; and

g) transferring packets to or from the terminal using only the second active communication session to effect the communications with the at least one communication device.

10 34. The method of claim 33 further comprising transferring the packets to or from the network proxy using the first and second active communication sessions to effect the communications with the at least one communication device prior to using only the second active communication session.

15 35. The method of claim 34 further comprising receiving second selection indicia from the terminal and stopping use of the first active communication session to transfer the packets based on the second selection indicia.

36. The method of claim 29 wherein the communication sessions are tunneling sessions with the network proxy.

20 37. The method of claim 29 wherein the terminal's communications with the plurality of access networks are based on disparate communication technologies.

38. A network proxy for facilitating packet communications between a terminal and at least one communication device comprising:

a) communication circuitry that facilitates communications with the plurality of access networks; and

52829-28

17

b) a control system associated with the communication circuitry wherein the control system:

i) establishes a plurality of communication sessions via the plurality of access networks with the terminal,

5 ii) receives selection indicia based on one or more factors related to the access networks pertaining to cost or performance from the terminal identifying one of the plurality of communication sessions to be a first active communication session;

iii) transfers packets to or from the terminal using the first active communication session to effect communications with the terminal; and

10 iv) communicates with the at least one communication device on behalf of the terminal.

39. The network proxy of claim 38 wherein the control system further:

v) receives second selection indicia from the terminal identifying at least a second one of the plurality of communication sessions to be a second active communication session wherein there are at least first and second active communication sessions; and

15

vi) transfers packets to or from the terminal using the first and second active communication sessions to effect the communications between the terminal and the at least one communication device.

20 40. The network proxy of claim 39 wherein the packets transferred using the first active communication session carry information different than carried in the packets transferred using the second active communication session.

41. The network proxy of claim 39 wherein the packets are duplicated and sent over both the first and second active communication sessions.

52829-28

18

42. The network proxy of claim 40 wherein the control system is further adapted to:

vii) receives switch indicia from the terminal indicating a need to switch from the first active communication session;

5 viii) receives the second selection indicia from the terminal identifying at least a second one of the plurality of communication sessions to be the second active communication session; and

ix) transfers packets to or from the terminal using only the second active communication session to effect the communications with the at least one communication device.

43. The network proxy of claim 42 wherein the control system further transfers the packets to or from the network proxy using the first and second active communication sessions to effect communications with the at least one communication device prior to using only the second active communication session.

44. The network proxy of claim 43 wherein the control system further receives the second selection indicia from the terminal and stop use of the first active communication session to transfer the packets based on the second selection indicia.

45. The network proxy of claim 38 wherein the communication sessions are tunneling sessions with the network proxy.

46. The network proxy of claim 38 wherein the terminal's communications with the plurality of access networks are based on disparate communication technologies.

47. One or more computer hardware storage media having stored thereon executable instructions which, when executed by one or more processors, cause the one or more processors to:

52829-28

19

establish a plurality of communication sessions via a plurality of access networks, with a network proxy, which facilitates communications between a terminal and at least one communication device;

5 select one of the plurality of communication sessions to be a first active communication session, wherein the selection is based on one or more factors relating to the access network pertaining to cost or performance;

identify the first active communication session to the network proxy; and

10 transfer packets to or from the network proxy using the first active communication session to effect communications with the at least one communication device.

48. The one or more computer hardware storage media as recited in claim 47, wherein the instructions further cause the one or more processors to:

15 select at least a second one of the plurality of communication sessions to be a second active communication session wherein there are at least first and second active communication sessions; and

transfer packets to or from the network proxy using the first and second active communication sessions to effect the communications with the at least one communication device.

20 49. The one or more computer hardware storage media as recited in claim 48, wherein the packets transferred using the first active communication session carry information different than information carried in the packets transferred using the second active communication session.

25 50. The one or more computer hardware storage media as recited in claim 48, wherein the instructions further cause the one or more processors to duplicate the packets and send duplicated packets, respectively, over both the first and second active communication sessions.

52829-28

20

51. The one or more computer hardware storage media as recited in claim 47, wherein the one or more factors related to the access networks comprise at least communication errors.

52. The one or more computer hardware storage media as recited in claim 47, wherein the selection is based on one or more factors related to the access networks pertaining to cost or performance; and

the one or more factors related to the access networks comprise at least transmission rate.

53. The one or more computer hardware storage media as recited in claim 47, wherein the selection is based on one or more factors related to the access networks pertaining to cost or performance; and

the one or more factors related to the access networks comprise at least quality of service.

54. The one or more computer hardware storage media as recited in claim 47, wherein the selection is based on one or more factors related to the access networks pertaining to cost or performance; and

the one or more factors related to the access networks comprise at least one or more rate plans associated with the access networks.
