A validated healthcare facility cleaning and sanitizing system provides a comprehensive and systematic approach to cleaning and sanitizing practices at a hospital or other healthcare facility. The validated hospital cleaning system identifies hospital vectors of contamination; that is, sources through which hospital acquired infections (HAIs) may be spread. The validated system defines a plurality of modules within a healthcare facility, each having an associated cleaning process map designed to meet the particular cleaning and/or sanitizing needs and challenges faced by that module. Various stages of the cleaning process map include validation points, at which certain parameters designed to ensure proper cleaning and/or sanitizing of the module are verified.
Fig. 1
Fig. 2B
Clean Patient Room

Patient in Room

Patient discharge

IF NEEDED: Visually scan room and remove any visible soils (e.g., blood spots, etc.) with a disposable wipe.

Get saturated blue cloth.

Clean mirror w/ blue cloth, dry with paper towel.

Clean soap and paper towel dispensers.

Wipe instruments and bedrails.

Wipe HTP - light switch, door knob, phone, TV, call cord, etc.

Wipe all furniture, stools, tables, counters, etc.

Wipe outside and inside of all trash cans.

Used cloth to used blue cloth bag.

Get trash bags from station.

Install new can liners (red, garbage, linen). DO NOT leave spares in bottom of can.

New Targeting Methodology

- Pre-mark HTO prior to cleaning
- After cleaning, analyze each HTO to determine % of area cleaned.

Cleaning HTO’s in patient room

- Paramount to providing Safe & Protected Environment for patient & healthcare workers
- Best practices focuses on cleaning these points to help improve patient safety & reduce risk of HAI’s

Operational Efficiency

**Observations**
Changing behavior takes right tools, time and reinforcement. Observation assists in determining where additional training is necessary.

**Safety Recommendations:**
- Perform regular audits to minimize labeling violations
- Train on Contact Isolation signage & product wipe usage (cases where wipes inappropriately used)
- Training to prevent food/drink on carts
- Provide 5S & visual mgmt techniques to organize carts to minimize cross contamination
- Cross contamination training (prevent redipping cloths)
- Train on proper use of PPE

**Product Usage Recommendations:**
- Train on appropriate disinfectant change out and importance
- Use mops according to training and icons

VALIDATED HOSPITAL CLEANING AND SANITATION PRACTICES

CROSS REFERENCE TO RELATED APPLICATIONS

[0001] This application is a continuation of U.S. patent application Ser. No. 13/369,056, filed Feb. 8, 2012, which is a continuation in part of U.S. patent application Ser. No. 12/432,277, filed Apr. 29, 2009, which claims the benefit of U.S. Provisional Application Ser. No. 61/125,922 filed Apr. 30, 2008, the entire contents of each of these applications are incorporated herein by reference.

TECHNICAL FIELD

[0002] The disclosure relates to cleaning and sanitizing practices at a hospital or other healthcare facility.

BACKGROUND

[0003] Despite improvements in hand hygiene, stricter compliance requirements, and efforts to optimize isolation practices, hospitals and other healthcare facilities are losing the war on nosocomial or Hospital Acquired Infections (HAIs). A hospital acquired infection is an infection acquired in a hospital or other healthcare facility by a patient admitted for some reason other than that specific infection. Hospital acquired infections may include infections appearing 48 hours or more after hospital admission or within 30 days after discharge. They may also include infections due to transmission from colonized healthcare workers, or occupational exposure to infection among staff of the facility. Although the majority of hospital acquired infections are preventable, sadly their incidence has only increased.

[0004] Hospital acquired infections have become more rampant as antibiotic resistance spreads. Many factors contribute to the increased incidence of hospital acquired infections among hospital patients. For example, hospitals house large numbers of people who are sick and therefore have weakened immune systems. Medical staff move from patient to patient and see many patients a day, providing a way for pathogens to spread. Research indicates that hand hygiene practices are followed only 40% of the time by healthcare workers, even after exhaustive process improvements and training efforts. Many medical procedures, such as surgery, injections, and other invasive procedures bypass the body’s natural protective barriers, providing entry points for pathogens. The wide-spread use of antibiotics has contributed to the emergence of resistant strains of microorganisms in healthcare facilities and well as in the community.

[0005] Nearly ¼ of surfaces in patient rooms are contaminated even after housekeeping has been completed. Many high touch objects in the patient room, such as doorknobs, bedrails, telephone, etc. are continuously re-contaminated. Patients and healthcare workers are thus exposed to many sources for potential pathogen transmission within a hospital room.

[0006] In addition, between 70% and 90% of incoming patients carrying Methicillin-Resistant Staphylococcus aureus (MRSA) or Vancomycin-Resistant Enterococci (VRE) are never identified and isolated. Many hospitals are unaware that MRSA lingers on patient room surfaces long after the colonized patient is discharged. Doctors and nurses carry MRSA on their lab coats and uniforms 65% of the time, potentially passing this organism to other patients or the environment.

[0007] It has been estimated that 1 out of every 20 patients contract hospital acquired infections. This translates to nearly 2,000,000 patients each year. By 1995, deaths from documented hospital acquired infections had escalated to almost 90,000 per year for an average of $345 per hospital. The costs associated with hospital acquired infections are significant. The cost to treat hospital acquired infections has been estimated to reach $30 to $50 billion per year. The average additional hospital costs for a patient contracting a hospital acquired infection is $15,275.

[0008] Although certain individuals, such as the critically ill, the elderly, young children and those with compromised immune systems are at greater risk, no patient is immune from the risk of acquiring an infection during a doctor’s visit or hospital stay.

SUMMARY

[0009] In general, the disclosure relates to a comprehensive and systematic approach to cleaning and sanitizing practices at a hospital or other healthcare facility.

[0010] In one example, the disclosure is directed to a system comprising at least one input device that receives collected data entered by a user, the collected data based on monitored validation points within a plurality of cleaning process maps for the healthcare facility, each of the cleaning process maps corresponding to a different one of a plurality of modules within the healthcare facility and defining housekeeping procedures associated with the corresponding module, a server computer that receives the collected data, a database coupled to the server computer that stores the collected data from the healthcare facility in association with hospital data that uniquely identifies the healthcare facility, that stores module data that defines each of the plurality of modules within the healthcare facility, and that stores the plurality of cleaning process maps in association with the corresponding module data, an analysis application resident on the server computer that analyzes the collected data and generates therefrom validation data indicative of adherence to the housekeeping procedures within the healthcare facility, and a reporting application resident on the server computer that generates reports that characterize the cleanliness of the healthcare facility based on the collected data, the validation data, the hospital data and the module data, each cleaning process map further including a storage process and a validation process, the storage process defining storage conditions for cleaning products, tools, and textiles, the validation process defining one or more of the validation points indicative of cleanliness of the associated module within the healthcare facility, the validation process further defining a monitoring procedure for each of the one or more validation points and identifying corrective action in the event that one or more of the validation points are not satisfied.

[0011] In another example, the input device includes one or more of a laptop computer, a personal digital assistant, a mobile device, a mobile phone, a iPod, an iPhone, an iPod touch, or an iPad. In another example, the system may include a plurality of input devices. In another example, the input device further may further include at least one processor, a user interface, and a validation application that, when executed by the processor, causes one or more screens to be presented on the user interface through which a user may
enter the collected data. In another example, the validation application may further, when executed by the processor, causes one or more screens to be presented on the user interface through which a user may enter data concerning whether one or more high touch points were cleaned. In another example, the validation application may further, when executed by the processor, causes one or more screens to be presented on the user interface through which a user may enter data concerning whether one or more high touch points were cleaned. In another example, the validation application may further, when executed by the processor, causes one or more screens to be presented on the user interface through which a user may enter data concerning whether one or more high touch points were cleaned.

The details of one or more examples are set forth in the accompanying drawings and the description below. Other examples, features, and advantages will be apparent from the description and drawings, and from the claims.

**BRIEF DESCRIPTION OF DRAWINGS**

[0013] FIG. 1 is a diagram illustrating a vector wheel that describes hospital contamination vectors from a patient-centered perspective.

[0014] FIG. 2A is a block diagram illustrating an example environment within which the validated hospital cleaning system may be used.

[0015] FIG. 2B is a block diagram illustrating an example hospital or other healthcare facility.

[0016] FIG. 2C is a block diagram illustrating an example breakdown of a hospital into modules and the processes associated with each module.

[0017] FIG. 3 is a block diagram illustrating an example of a generalized validation process flow map.

[0018] FIGS. 4A-4G are flow charts illustrating an example validation process flow map for the patient room module.

[0019] FIG. 5 is a flow chart illustrating an example storage process map for the patient room module.

[0020] FIGS. 6A-6F are a chart illustrating example validation processes for the patient room module.

[0021] FIG. 7 is a flow chart illustrating an example high touch object cleaning validation process for the patient room module.

[0022] FIGS. 8A-8M show example reports that may be generated by reporting module for the patient room module.

[0023] FIG. 9 shows an example input device on which an application icon for a validation process audit application is displayed.

[0024] FIGS. 10-15 show example screens that may be displayed on an input device by the validation process audit application.

[0025] FIGS. 16-18 show example screen shots reports that may be generated by reporting module.

[0026] FIG. 19 is a block diagram illustrating an example input device including a validation process audit application.

**DETAILED DESCRIPTION**

[0027] In general, the disclosure relates to comprehensive and systematic approach to cleaning and sanitizing practices at a hospital or other healthcare facility. A validated hospital cleaning process identifies hospital vectors of contamination; that is, possible sources through which hospital acquired infections (HAI s) may be spread. The validated process defines a plurality of modules within a hospital or other healthcare facility, each having an associated cleaning process map designed to meet the particular cleaning and/or sanitizing needs and challenges faced by that module. The cleaning process map for each module may be based, for example, on scientifically validated best practices of clearly defined cleaning processes. Various stages of the cleaning process map include validation points, at which certain parameters designed to ensure proper cleaning and/or sanitizing of the module are verified.

[0028] The validated hospital cleaning process may address clinical and cleaning procedures across many fronts within the hospital. The validated process may include some or all of the following: objective assessments, audits and measures; data collection, hazard analysis and critical control point identification; efficient and effective processes and protocols; training and interventions that change behaviors; consistent, automated and invisible monitoring; innovative products and technologies; clinical experts and personalized support services; quality assurance practices; implementation of best practices; and cleaning through clinical improvements that may reduce the incidence of HAI s.

[0029] FIG. 1 is a diagram illustrating a vector wheel that describes hospital contamination vectors from a patient-centered perspective. At the center of the vector wheel is the patient. Moving from the center toward the outside of the vector wheel moves from a patient’s immediate surroundings (e.g., patient to patient bed to patient room) into areas of a hospital that are increasingly shared by other patients, healthcare workers and/or the public. The vector wheel of FIG. 1, for example, moves from the patient at the center to the patient bed, patient room, common areas (such as nursing stations), treatment rooms (such as radiology or physical therapy), general facilities (such as waiting rooms, cafeterias, hallways, etc.) and finally to the patient’s home and the world at large.

[0030] The vector wheel also illustrates the contamination vectors within a hospital or other healthcare facility that may be identified by the validated process described herein. The contamination vectors are represented as “slices” on the vector wheel and may include, in no particular order:

[0031] (1) Skin: healthcare worker hand hygiene and skincare

[0032] (2) Hard surfaces: Permanent (bedrails, handles, floors, walls, etc.); mobile (carts, IV stands, wheelchairs, etc.)

[0033] (3) Soft surfaces: decorative and infrequently cleaned (partition curtains, drapes, carpet, wallpaper, etc.)

[0034] (4) Instruments: surgical procedure instruments; diagnostic procedure instruments (endoscopes, etc.); general instruments (stethoscopes, thermometers, etc.)

[0035] (5) Human transmission: patients, visitors & non-healthcare workers, healthcare workers & specialists. This may also be expanded to include service and therapy animals.

[0036] (6) Air quality: critical patient care and general, special considerations for construction and renovation

[0037] (7) Water quality: patient care and contact, cleaning and/or sanitization (other) Building Infrastructure & Construction: mold and contaminates in walls, ducts, etc.; Pest Control; Patient Personal Care Soft Surfaces: linens, towels, gowns, etc.

[0038] Different areas of the hospital may require different levels of cleaning and/or sanitization. These may be classified, for example, as “clinical” and “clean.” The vector wheel of FIG. 1 indicates an example distribution of areas within a healthcare facility that may be designated as clinical or clean.
For example, “clinical” may be defined as an area where antimicrobial products such as EPA registered disinfectants or antimicrobial skin care products such as surgical scrubs or healthcare personnel hand washes should be used. “Clean” may be defined as areas where general purpose cleaning products and hand soaps may be used. Example “clean” areas on the vector map are shaded a dark gray while example “clinical” areas are shaded lighter gray.

Other areas on the vector wheel of FIG. 1 may require quality assurance practices. For example, hand hygiene and collocation data monitoring is important for healthcare workers, sterilization controls are important for surgical instruments and air quality and particle count is important for building infrastructure and construction.

FIG. 2A is a block diagram illustrating an example communications environment 20 within which the validated hospital cleaning system of the present disclosure may be used. One or more hospitals or other healthcare facilities 22A-22N are coupled via a network 24 to a server computer 30. Network 24 may be, for example, a dial-up connection, a local area network (LAN), wide area network (WAN), the internet, etc. The connection may be wired or wireless. Server computer 30 may be coupled to a local server computer at each hospital 22A-22N via network 24 to receive data related to the validated hospital cleaning system that is stored on local storage media at each hospital. Server computer 30 may also send commands, instructions, software updates, etc. to each hospital via network 24. Server computer 30 may receive data or otherwise communicate with the hospitals on a periodic basis, in real-time, upon request of server computer 30, or at any other appropriate time.

The data received from hospitals 22A-22N, as well as other data associated with the operation of the validated hospital cleaning system, may be stored on a database 40. Database 40 may store, for example, hospital data 42A-42N associated with each of the hospitals 22A-22N, respectively; module data 43A-43N associated with each of the hospitals 22A-22N, respectively; process map data 44A-44N associated with each of the hospitals 22A-22N, respectively; user data 45A-45N associated with each of the hospitals 22A-22N, respectively; storage data 46A-46N associated with each of the hospitals 22A-22N, respectively; patient data 47A-47N associated with each of the hospitals 22A-22N, respectively; device data 48A-48N associated with each of the hospitals 22A-22N, respectively; etc. Because each hospital or healthcare facility may perform different functions and have different physical areas within the healthcare facility, module data 42A-42N may be specific to the respective healthcare facility 22A-22N.

Process map data 43A-43N may include, for example, information that addresses the cleaning and/or sanitizing requirements for each module within the respective hospital 22A-22N. User data 44A-44N may include, for example, information concerning those persons or entities authorized to access the reports generated by the validated hospital cleaning system for the respective hospital 22A-22N. Storage data 45A-45N may include, for example, information that addresses proper storage and validation processes for the equipment, tools, cleaning and/or sanitizing products associated with each module for the respective hospital 22A-22N. Collected data 46A-46N may include, for example, any data collected at the respective hospital 22A-22N relevant to the validated hospital cleaning system. Collected data 46A-46N may also include baseline data corresponding to the status of monitored validation points before implementation of the validated hospital cleaning system/method. Validation data 48A-48N may include, for example, the results of any analysis of collected data 46A-46N received from the respective hospital 22A-22N.

Server computer 30 includes an analysis application 32 that analyzes the collected data 46A-46N received from each of hospitals 22A-22N and stores the results for each hospital 22A-22N as validation data 48A-48N, respectively. A reporting application 34 generates a variety of reports that present the validation data generated by analysis application 34. Reporting application 34 may generate a variety of reports to provide users with both qualitative and quantitative data regarding the cleanliness of their hospital, and/or to compare data over time to determine whether improvement has occurred. Reporting application 34 may also users to benchmark multiple hospitals or other healthcare facilities. It may also be an assessment tool that is used post cleaning to assess the effectiveness of the use of the validated cleaning system/process and to determine whether the proper procedures are being followed.

Reports 49A-49N may be stored in database 40. Examples of the reports that may be generated by reporting application 34 are described with respect to FIGS. 8A-8M. Reports 49A-49N may be accessed by various authorized users 50 over network 52. Network 52 may be the same as network 24 (in the case of the internet, for example) or may be a different network.

FIG. 2B is a block diagram illustrating an example hospital or other healthcare facility 22. Each hospital 22 includes a plurality of modules 124A-124N (hereinafter referred to generally as modules 124). As discussed above, modules 124 may be physical modules associated with physiological areas of hospital or may be functional modules associated with functions carried out within a hospital. Each hospital 22 also includes a hospital server computer 28 that communicates with the server computer 30. Hospital 22 may also include a variety of input devices 26 into which collected data relevant to the validated hospital cleaning system is entered into the system. Input devices 26 may include, for example, one or more networked computing stations, laptop computers, personal digital assistants, cellular phones, mobile phones, smart phones, laptop computers, tablet computers, personal digital assistants (PDAs), portable media players (such as the iPod, iPod touch, iPhone, or iPad manufactured
by Apple, Inc., or other portable media players), any other mobile or stationary computing devices, whether wired or wireless, or any other suitable device or combination of devices capable of receiving the collected data in electronic form. The collected data may be stored in a local hospital database 40. Alternatively, the collected data may be sent directly to server computer 30 to be stored in database 40.

[0048] In one example, local hospital database 24 may store all of the data types described above with respect to database 40 associated with that particular hospital 22. Hospital server computer 26 (or other local computer) may also include local analysis and reporting applications such as those described above with respect to analysis and reporting applications 32 and 34. In that case, reports associated with that particular hospital may be generated and viewed locally, if desired. In another example, all analysis and reporting functions are carried out remotely at server computer 30, and reports are viewed remotely over network 52, such as the Internet. In other examples, some hospitals 22 may include local storage and/or analysis and reporting functions while other hospitals 22 rely on remote storage and/or analysis and reporting. Thus, although the general case of data being stored at the server database 40 and analysis/reporting being carried out by the server computer 30 is described herein, it shall be understood that these storage, analysis and reporting functions may also be carried out locally or at some other location, and that the disclosure is not limited in this respect.

[0049] FIG. 2C is a block diagram illustrating modules 124A-124N within a hospital 22 or other healthcare facility and the processes associated with each module. The validated hospital cleaning process 120 (hereinafter referred to generally as “validation process”) defines a plurality of modules 124A-124N within a hospital. Modules 124A-124N may be physical modules associated with physical areas of hospital or may be functional modules associated with functions carried out within a hospital. Physical modules may include, for example, patient rooms, critical care areas, central sterile processing, operating rooms, food service, bathrooms, laundry rooms, floors, etc. Functional modules may include, for example, patient skincare, wound cleaning, hand hygiene, etc.

[0050] Each module 124A-124N is associated with a cleaning process map 126A-126N, respectively. The associated cleaning process map 126A-126N addresses the contamination vectors (FIG. 1) that are relevant to that module. For example, for the patient room cleaning module, the vectors addressed may include, among other things, skin (healthcare worker hand hygiene and skin care), hard surface (disinfection of mobile and permanent surfaces), soft surfaces (cleaning and where appropriate sanitization of privacy curtains), etc.

[0051] Each cleaning process map 126A-126N addresses the cleaning and/or sanitizing requirements of the associated module. For example, the patient room cleaning process map may include processes for stocking the patient room cleaning station, how cleaning personnel are notified of patient discharge, preparation of room for cleaning, removal of garbage, removal of linen, cleaning of bathroom, cleaning of the patient room, floor cleaning, and restocking of cleaning station, etc. The process map(s) associated with other module(s) within the hospital will include processes unique to that module aimed toward proper cleaning and/or sanitization practices and consideration of the relevant contamination vectors within that module.

[0052] Each cleaning process map 126A-126N lists all components and steps in the cleaning process. Validation points are inserted at certain identified process steps in the process flow map for each module. The validation points are inserted for identified process steps which, if not performed properly, there is a potential increased incidence of an unclean room or HAI infection risk.

[0053] As is also shown in FIG. 2C, each cleaning process map 126A-126N is associated with storage processes 128A-128N and validation processes 130A-130N, respectively. Storage processes 128A-128N refer to the proper storage conditions for the equipment, tools, cleaning and/or sanitizing products associated with each module. For example, the storage process map for the patient room module may include the proper storage conditions for the patient room cleaning station and tools, quaternary disinfectant (quat), textiles, miscellaneous station supplies such as trash bags, etc., a toilet bowl brush, etc. The storage process map(s) associated with other module(s) within the hospital will include product/equipment storage processes unique to that module aimed toward proper cleaning and/or sanitization practices within that module.

[0054] The validation processes 130A-130N refer to processes carried out at specified critical control points during the cleaning process, herein referred to as validation points. These validation points are identified points during the cleaning process at which certain parameters that may ensure proper cleaning and/or sanitizing of the module are verified.

[0055] For example, the validation processes for the patient room module may include verifying that a dispensed disinfectant solution contains the proper concentration of active ingredient, verifying that certain hard surfaces are contacted with a disinfectant impregnated cloth for a predetermined period of time, use of waterless sanitizer during hand washing, washing of hands both pre- and post-room cleaning, station cleaning, etc. The validation process map(s) associated with other module(s) within the hospital will include validation processes unique to that module aimed toward proper cleaning and/or sanitization practices within that module.

[0056] The validation processes for each module may be developed using the following considerations. Proper cleaning requires effective products and practices, training and monitoring. Effective disinfection and sterilization requires proper cleaning and storing, effective products and practices, training, compliance and monitoring. Clinical solutions require proper cleaning, effective disinfection and sterilization, innovative products and technology, process improvements, data analysis, training, compliance and monitoring. Depending upon the module and the vectors affecting that module, any number of these considerations may affect the resulting validation process.

[0057] FIG. 3 is a block diagram illustrating an example of a generalized validation process flow map 130. Each validation point in a cleaning process map will include its own associated validation process flow map 130. The validation process flow map 130 identifies parameters 134 that must be met during the validation process. For example, the patient room module cleaning process flow map may include a validation point when disinfectant is dispensed. The parameters to be met may include, for example, requirements that the concentration of active ingredient within the disinfectant falls within certain limits, that proper disinfectant concentration is delivered to the relevant surfaces, elimination of cross con-
tamination, etc. Other validation points may include parameters relevant to that particular point in the module cleaning/sanitizing process.

[0058] The process flow map also includes monitoring procedures 136 which may be used to verify that the parameters are satisfied. These monitoring procedures 136 may include a definition of one or more of the following:

[0059] What (136A): the monitoring procedure(s) which may be used to determine whether the parameters are satisfied (e.g., active ingredient titration or test in the case of dispensing disinfectant).

[0060] How (136B): the test or verification procedure which may be used to determine whether the parameters are satisfied (e.g., definition of titration procedure or test, use of visual indicators, verification methods such as surface cultures, time-based monitoring, etc.)

[0061] Frequency (136C): how often should the monitoring procedure be performed (e.g., after each cleaning, daily, weekly, monthly, etc.).

[0062] Who (136D): who will perform the monitoring procedure (e.g., hospital environmental services manager, service technician, cleaning personnel, independent vendor, etc.).

[0063] For example, the monitoring procedures for the validation point when disinfectant is dispensed may include regular dispenser validations and laboratory dispenser reliability testing to ensure that the concentration of active ingredient within the disinfectant falls within certain limits, laboratory testing on microfiber or other cleaning cloths to ensure that proper disinfectant concentration is delivered to the relevant surfaces (in other words, ensuring that the cloths do not absorb too much of the disinfectant), use of color coded cloths, carts with designated “clean” and “dirty” areas, and single use mops to eliminate cross contamination.

[0064] The results of the monitoring procedure(s) 136 are referred to herein as collected data. The collected data may be stored on the local hospital database 24 (see FIG. 2B) until such time as it is to be sent to server computer 30 (see FIG. 2A). Once received by server computer 30, collected data from each hospital 46A-46N is stored on server database 40. Examples of collected data may include without limitation one or more of the following data types: titration or other test results; disinfectant/sanitizer or other chemical product concentrations; dispensed detergent amounts; dispensing times, dates, and sequences; water temperatures; autoclave temperatures; chemical product types; wet contact times; results of microbial cultures, including type and number of organisms in a sample; bioluminescence readings, protein detection, particle counts; and/or other information relevant to the monitoring procedures at each module.

[0065] As is further shown in FIG. 3, a validation procedure 140 is performed on the collected data to verify whether the parameters of the validation point were satisfied. The validation procedure is performed by an analysis application, such as analysis application 32 resident on server computer 30 (see FIG. 2A). In other examples, the local hospital server 28 (FIG. 2B) or other local hospital computer may include a local analysis application that performs the validation process 140. The validation procedure may include a comparison of the collected data with the predetermined parameters.

[0066] The results of the validation procedure is referred to herein as validation data. The validation data may be stored on the local hospital database for those installations where the local hospital server or other local hospital computer includes a local analysis application. Validation data 48A-48N for each hospital 22A-22N may also be stored on the server database 40 (see FIG. 2A).

[0067] If the analysis application 32 validation procedure indicates that the validation parameters were not satisfied, the validation process flow map may include a corrective action process 142. Corrective action 142 may include equipment troubleshooting, retraining of personnel in proper cleaning/sanitizing procedures, etc.

[0068] The validated hospital cleaning system/process may analyze the hospital data 41A-41N, module data 42A-42N, process map data 43A-43N, user data 44A-44N, storage data 45A-45N, collected data 46A-46N, and validation data 48A-48N either alone or in combination with each other to characterize cleanliness of the hospital or healthcare facility 22A-22N. The validated hospital cleaning system/process may also generate reports 49A-49N that present the data in various formats and present the analysis for review by a site manager, corporate or government entity or other body responsible for oversight of the healthcare facility or of the validated hospital cleaning process.

[0069] FIGS. 4A-4G are a flow chart illustrating an example validation process flow map for a patient room module. As shown in the symbol key (164) in FIG. 4A, the process flow map may include, for example, process main steps, process sub-steps, tool and item lists, options, tools or guides lists, identification of what to evaluate at particular steps, and validation points.

[0070] FIG. 4A shows an example of a “Determine Cleaning Schedule” main process step (152). This may be simply to follow the hospital’s current cleaning practices or may be another cleaning schedule as determined by best practices or other means. A listing of tools and products (154) needed for cleaning based on the schedule and room information (e.g., size, equipment in room, furniture in room, etc.) may be included. A hospital room cleaning brochure/inpatient welcome kit (156) to be provided to each patient may also be included.

[0071] FIG. 4A also shows an example of a “Stock Cleaning Station” process step (158). This may include several sub-steps. The various tools, consumables, textiles, required during each scheduled cleaning may be stocked onto the cleaning station and laundry nets may be set up. A list/checklist of tools (see FIG. 4A) and other ancillary products may be provided.

[0072] The dust pan may be replaced with a new dust bag. Personal protective equipment (PPE), such as gloves, masks, eye-protection, gowns, etc. is stocked onto the cleaning station. The appropriate cleaning solutions are dispensed and measured. Cloths and mops are saturated with cleaning solution. A room cleaning checklist and/or schedule may be mounted onto the cleaning station. The room cleaning checklist may include a list of what to clean and what to inspect during the patient room cleaning process. The textile inventory control plan may also be in place to keep track of textiles (sheets, towels, gowns, etc.) going into or out of the patient room.

[0073] The portion of the patient room validation process shown in FIG. 4A includes two validation points; validation point (159A) occurs when the cleaning solution(s) are dispensed and measured. At this validation point, the relevant parameters of the cleaning solution(s), e.g., the amount of product dispensed, the type of product dispensed, the product concentration, and/or the dispenser accuracy may be moni-
tored and, if the parameters are met, verified. Validation point (159B) occurs when the room cleaning checklist is mounted on the cleaning station. At this validation point, the cleaning personnel may verify that all tools/equipment are on the clean side of the cleaning station.

[0074] At main step “Notification of Patient Discharge” (160) includes some type of notice to cleaning personnel that a patient has been discharged. If the room is to be cleaned before a patient is discharged, this step may be skipped. The cleaning station is then transported to the patient room for cleaning (162).

[0075] FIG. 4B shows an example of a “Prepare Room for Cleaning” main process step (170). This may include several sub-steps. For example, cleaning personnel may review a door card or signage for contact precautions to determine PPE needs. For example, cleaning personnel may be notified if a patient having certain conditions occupied or is currently occupying the room so that personal protective precautions may be taken. The “Prepare Room for Cleaning” process (170) may prompt cleaning personnel to wash and/or sanitize their hands and put on the relevant PPE. Validation point (171) occurs at this pre-room cleaning hand washing step.

[0076] FIG. 4B also shows an example of a “Remove Garbage” main process step (172). Main process step “Remove Garbage” may include removal of infectious waste, removal of non-infectious waste, and disposal of garbage per current hospital procedures or other best practices.

[0077] FIG. 4C shows an example of a “Remove Linen” main process step (180). Main process step “Remove Linen” may include removal of soiled linen and disposal of linen as per current hospital procedures or other best practices. Procedures for contaminated linen and/or other laundry protocols and procedures may also be included. Validation point (181) occurs at the laundry, where validation of various laundry parameters to ensure that laundry is properly cleaned and sanitized.

[0078] FIG. 4C also shows an example of a “Clean Bathroom” main process step (182). Main process step “Clean Bathroom” may include several sub-steps. The process may include getting a saturated cloth and brush/caddy and toilet product from the cleaning station, cleaning the mirror, cleaning soap and paper towel dispensers, and cleaning the light switch and the door knob. The cleaning product may also be sprayed or otherwise applied to the surfaces rather than using a saturated cloth. If the tub/shower is visibly dirty, the process may include running hot water for a predetermined period of time. The appropriate toilet cleaning/sanitizing product is placed in the toilet and left for a specified period of time. The sink, bathroom fixtures including handicap rails, tub/shower, shower curtain and toilet seat/bowl/exteriors/fixtures are cleaned. Several critical control points, here referred to generally as validation points (183A-183D) may occur during the “Clean Bathroom” process step. These validation points may include validation of proper hard and/or soft surface cleaning procedures, such as wet contact time, culture results, photo-luminescent or chemiluminescent indicators, etc.

[0079] The “Clean Bathroom” process step (182) may also include cleaning/wiping of the outside and/or inside of the bathroom trash can. The toilet may be flushed, or, in the alternative, the toilet may be left unflushed, thus leaving the colored water produced by the toilet cleaner present in the bowl as a visual indicator that the toilet has been cleaned. After cleaning the bathroom, the cloth used to clean the mirrors, etc. is placed in the dirty cloth bag. The toilet caddy/brush is returned to its storage spot on the cleaning station. The paper towel from the cleaning the mirror, etc. is placed in the trash. A notification that the bathroom was cleaned, such as colored water in the toilet bowl, wrap on toilet seat, etc. may also be included.

[0080] In addition, to the validation points (183A-183D) shown in FIG. 4C, other validation points associated with other surfaces that are now or in the future determined to be important contamination vectors may also be incorporated into the “Clean Bathroom” process step (or any other validation process associated with any of the modules, for that matter).

[0081] The “Clean Bathroom” process step (180) thus includes cleaning/wiping of some or all of a plurality of high touch points (HTP) (also referred to herein as high touch objects (HTO)). The high touch points for a bathroom may include, for example, the bathroom light switch, bathroom door knob, sink, toilet top, toilet handle, toilet hold/rolls, bed pan cleaner, and/or any other physical item or area in a patient bathroom that may be frequently re-contaminated.

[0082] FIG. 4D shows an example of a “Clean Patient Room” main process step (190). This process step may diverge depending upon whether the patient still occupies the room (left branch) or whether the patient has been discharged (right branch). If the patient still occupies the room (regardless of whether the patient is physically present in the room at the time of cleaning) the process may include visually scanning the room and removing any visible soils, such as blood spots or other stains/soils, with a disposable wipe or other appropriate soil cleaning method. At this point the process may include getting a saturated cloth from the cleaning station, cleaning the mirror, soap, and paper towel dispenser, and wiping any instruments, the bed, and the bed rails. Other cleaning methods, such as applying the cleaning/sanitizing product to the surfaces by spray or other means could also be used.

[0083] The “Clean Patient Room” process step (patient in room) may also include cleaning/wiping of some or all of a plurality of high touch points (HTP). The high touch points may include, for example, the light switch, door knob, telephone, TV, call box, tray table, bedside table, bedrails, and/or any other physical item or area in a patient room that may be frequently re-contaminated. The “Clean Patient Room” process step (patient in room) may also include wiping of all furniture including stools, tables, chairs, counters, etc.

[0084] Validation point(s) (191A-191C) occur during the “Clean Patient Room” process step. Here, validation of various cleaning procedures parameters to ensure that the patient room is properly cleaned and sanitized are monitored. For example, the validation point(s) (191A-191C) may require that all relevant surfaces are contacted with a disinfectant impregnated cloth and remain wet for at least 10 minutes with disinfectant. Monitoring may be accomplished via visual inspection of how long surfaces remain wet, photo- or chemiluminescent indicators, adenosine triphosphate (ATP), culture, etc., to ensure that proper cleaning/sanitizing procedures were adequately performed.

[0085] The “Clean Patient Room” process step (patient in room) may also include placing the used cloth(s) to the used cloth bag, getting trash bags from the cleaning station, installing new toilet/caddy (infectious waste can, used linen can, trash can, etc.), restocking room linens and other room supplies as needed, and other process steps necessary to prepare the room for another patient. Cloths for different areas or modules may
be color coded, e.g., yellow cloths for bathroom, blue cloths for the patient room, etc., to reduce cross contamination between areas or modules.

Fig. 4E shows an example of a discharged branch of a “Clean Patient Room” main process step. This branch includes many of the sub-steps as the patient in room branch shown in Fig. 4D. However, certain steps may be performed after the patient has been discharged that may be undesirable when the room is occupied by a patient, such as dusting of high surface areas (ceilings, ceiling light fixtures, fans, etc.) and the wiping of walls and baseboards. Validation point(s) (193A-193C) are monitored to ensure that the patient room is properly cleaned and sanitized.

The “Clean Patient Room” process may also include a notification that the patient room has been cleaned, such as a note card, hallway sign, swing out, etc. (194).

Fig. 4F shows an example of a “Clean Floors” main process step (200). This step may include several sub-steps, including picking up of large objects with a dust pan or squeegee, setting up a wet floor sign, assembling a mop head on a mop, specific procedures for mopping the floor, specific procedures for returning used mop to soiled laundry net and replacing mop handle on cleaning station, storing of the squeegee/dust pan, etc.

Fig. 4G also shows an example of an “Exit Room” main process step (202). This step may include the sub-steps of completing a room cleaning inspection checklist, leaving the room cleaned notification, removal of PPE, and post-room cleaning hand washing/sanitizing. Validation points (203A-203B) occur during the removal of PPE and hand washing steps, to ensure proper handling and/or disposal of the PPE and to confirm proper post-room cleaning hand washing takes place.

Fig. 4H shows an example of a “Station Breakdown/Storage” main process step (210). This step may include wiping of cleaning station, placing of used cleaning cloths to the used linen bag, placing of leftover textiles (unused) in the used linen bag, sending of soiled textiles to the laundry, proper disposal of trash. This may also include rinsing of mop and cloths bins and allowing them to dry, rinsing of bowl brush and caddy and allowing them to dry. The station may be secured in a closet or store room. The closet may be restocked as needed. The process may also require cleaning personnel to file paperwork and/or checklists.

Validation point (211A) occurs when the cleaning station is wiped down with disinfectant. Here, validation of various cleaning procedures parameters to ensure that the patient room is properly cleaned and sanitized are monitored. For example, the validation point (211A) may require that all relevant surfaces of the cleaning station have been contacted with a disinfectant impregnated cloth and remain wet for at least 10 minutes (or other appropriate time corresponding with the disinfecting time of the product) with disinfectant. Monitoring may be accomplished via visual inspection of how long surfaces remain wet, photo-chemiluminescent indicators, adenosine triphosphate (ATP), culture, etc., to ensure that proper cleaning/sanitizing procedures on the cleaning station were adequately performed.

Validation point(s) (211B-211C) occurs at the laundry site, where monitoring and validation of proper laundry procedures are performed to ensure proper handling/cleaning/disinfecting of laundry articles. Different laundry articles, such as cleaning cloths, bed linens, towels, gowns, etc., may have different laundry validation procedures.

Fig. 5 is a flow chart illustrating an example storage process map for the patient room module (220). The storage process map for each module includes proper storage/handling procedures for all of the products, tools, and equipment used during the cleaning process map for that module. Thus, the storage process map for the patient room module may include storage/handling procedures for the patient room cleaning station and tools, any cleaners and/or disinfectants used during the patient room cleaning process, textiles needed during the room cleaning process, miscellaneous station supplies used during the room cleaning process, and mops or other cleaning equipment used during the room cleaning process. The storage process map may include storage conditions for each item, such as the storage location, conditions, temperature, maximum storage time, etc.

Figs. 6A-6F are a chart listing example validation processes for the patient room module (230). The validation points in the left-most column correspond to the validation points shown in the flow charts of Figs. 4A-4G. Fig. 6 shows, from left to right, identification of the validation point (corresponding to the like numbered validation point in Figs. 4A-4G), identification of the process step at which the validation point occurs, description of the monitoring procedure, including what, how, frequency, and who will perform the monitoring procedure, and identification of possible corrective action should the validation indicate that the process parameters were not satisfied. Although the flow chart of Fig. 6 illustrates validation processes for these validation points, it shall be understood that other or different validation points and their associated processes may also be used for the patient room module, and that the disclosure is not limited to or by the examples given herein.

Fig. 7 is a flow chart illustrating an example high touch object cleaning validation process 300 for the patient room module. It shall be understood that this process is one example that may be used with a particular high touch object, and that other high touch objects may have similar or different validation processes depending upon the particular requirements for each high touch object, and that the disclosure is not limited in this respect.

Process 300 includes various testing methods that may be used to evaluate the effectiveness of the room cleaning. The testing may be performed both before and after the patient's room has been cleaned. Process 300 begins with identification of the particular high touch object involved (302). For example, high touch objects for the patient room module may include the sink, the toilet handle, the toilet seat, the bed pan cleaner, the toilet hand holdrail, the bathroom door handle, the bed rail, the call button, the tray table, the bedside table, the telephone, and the room door knob.

One such test may include application of an indicator, such as a photoluminescent or chemiluminescent indicator, which is applied to a defined location on the high touch point prior to cleaning (304). Inspection of the indicator post cleaning may be used to determine whether the high touch object has been cleaned. In the patient room module, for example, the indicator would be applied in a well-defined manner to each of the high touch objects that are defined for that module. After completion of the cleaning procedure (310), the surface may be inspected with a black light to determine if the indicator was disturbed by the cleaning process (312). Training would be provided to hospital personnel on what constitutes a “passing” or “failing” result. For example, passing results may include complete removal of
the indicator or disturbance of a circular swirl pattern. Failing results may include an untouched indicator and/or no evidence of wiping.

[0098] Another test may include examination of culture counts as an indication of cleaning effectiveness. A surface sample of aerobic culture counts are collected at defined locations on the surface of the high touch object before (306) and after (314) completion of the cleaning process. Presence of aerobic bacteria may be used to quantify cleaning effectiveness. Threshold levels for “passing” or “failing” aerobic culture counts may be set, or the total aerobic culture count may be stored and reported.

[0099] Another test may include examination of adenosine triphosphate (ATP) levels as indication of cleaning effectiveness. Defined locations on the surface of the high touch object are swabbed before (308) and after (316) completion of the cleaning procedure (310). Presence of ATP correlates with presence of microorganisms, and thus may be used to quantify cleaning effectiveness. Threshold levels for “passing” or “failing” ATP levels may be set, or the total ATP level may be stored and reported.

[0100] Training/certification may be provided to the relevant personnel to help ensure that the methodologies of the validated hospital cleaning method are followed. Consistent application by trained personnel of the methodologies described herein helps to increase accuracy and reliability of the validated hospital cleaning methods. For example, detailed instructions concerning application of the indicator may include the delivery method with which the indicator is applied (e.g., pen, swab, etc.) and how the indicator should be applied (swirl pattern, dot, etc.) may be provided. Similarly, detailed instructions concerning collection of ATP or culture samples (size of swab or culture, etc.) may also be provided. Information regarding the specific location at which the indicator should be applied or from where the ATP or culture should be taken (faucet post vs. faucet handle; near end of faucet handle vs. far end of faucet handle; top or bottom of flange of toilet flush; back, left or right side of toilet seat; location on toilet hand rail, etc.) may also be provided.

[0101] The data collected from verification process 300, as well as from all of the other verification processes of the validated hospital cleaning method, may be input manually (such as for visual inspection of the indicator or ATP or culture counts) or automatically for those pieces of data obtained from automated equipment.

[0102] FIGS. 8A-8L show example reports that may be generated by reporting application 34 for the patient room module for a fictional healthcare facility, ABC Hospital. These reports may include, for example, detailed analysis and reporting on key metrics, including cleaning outcomes, behavioral observations, room cleaning efficiency, products/tools overview, dispenser analysis, staff knowledge, employee satisfaction, patient satisfaction, etc. The reports may benchmark current module practices across the entire database or across hospitals or other healthcare facilities. The reports may include trending of various key metrics over time, provide actionable improvement plans, and assess current practices relative to best practices and process critical control points. It shall be understood that the reports shown in FIGS. 8A-8L are exemplary only, and that other reports may also be generated for the patient room module, and that other reports may also be generated for other modules, each including reports on data relevant to those modules, and the disclosure is not limited in this respect.

[0103] FIG. 8A, for example, illustrates an example summary report for the fictional healthcare facility. The summary report shows a table having rows for each of continuous improvement and education, operational processes, hygiene outcome efficiency, and satisfaction. The data for each of these rows is shown across columns for the facility wide baseline, the previous period, and the current period.

[0104] FIG. 8B, for example, illustrates an example report including data regarding hygiene outcomes for the marking solution, indicating the percent of time high touch objects were cleaned. In this particular example, the data is broken down in overall high touch point cleaning, patient room cleaning, and bathroom cleaning, with columns for the facility wide baseline, the previous period and the current period. Also shown are data for the most cleaned high touch point, the most frequently missed high touch point and the percentage of time all high touch points are cleaned.

[0105] FIG. 8C, for example, illustrates an example report including detailed analysis of the percent of time high touch objects were cleaned. This table gives data for each individual high touch point for the facility wide baseline, the previous period and the current period.

[0106] FIG. 8D, for example, illustrates an example report that shows the detailed analysis of the percent of time high touch objects were cleaned for each individual high touch object in graphical form.

[0107] FIG. 8E, for example, illustrates an example report including data regarding hygiene outcomes for culturing of high touch points. The table shows percent occurrences where the post-cleaning reading was lower than the pre-cleaning reading. The report also shows which high touch point had the lowest average culture count and which had the high average culture count.

[0108] FIG. 8F, for example, illustrates an example report showing, in tabular form, analysis of the percent occurrences where the post-cleaning reading was lower than the pre-cleaning reading for each individual high touch point. This example report includes the data in graphical and tabular form.

[0109] FIG. 8G, for example, illustrates an example report showing, in graphical form, analysis of the percent occurrences where the post-cleaning reading was lower than the pre-cleaning reading for each individual high touch point.

[0110] FIG. 8H, for example, illustrates an example report detailing the number of hospital acquired infections by month over a period of time. In this example, the period September ‘08 may be the baseline (i.e., data taken before the validated hospital cleaning method was in place to establish a basis for comparison), whereas the period Jan ‘08 is the current period.

[0111] FIG. 8I, for example, illustrates an example report detailing operational efficiency for cleaning upon discharge. This table allows users to compare current operational efficiency with baseline operational efficiency to determine whether the operational efficiency associated with the validated hospital cleaning method is within acceptable limits or whether it favorably compares to the baseline operational efficiency.

[0112] FIG. 8J, for example, illustrates an example report detailing operational efficiency for disinfectant concentration as applied to surfaces for a previous cleaning cloth and dispenser and the current cleaning cloth and dispenser.

[0113] FIG. 8K, for example, illustrates an example report detailing operational efficiency for disinfectant concentration as dispensed by the current dispenser. The report indicates
whether the disinfectant concentration is within acceptable limits and whether it met the target concentration.

[0114] FIG. 8L, for example, illustrates an example report detailing operational efficiency with respect to behavior observations of cleaning personnel. This information can help to identify where additional training may be necessary if identified behaviors are not conforming to the methodologies of the validated hospital cleaning method.

[0115] FIG. 8M, for example, illustrates an example report providing a summary of recommended next steps that the hospital may take to improve their results in the future. Suggested next steps are given for each of continuous improvement and education, operational processes, hygiene outcome efficiency, and satisfaction.

[0116] FIG. 19 is a block diagram illustrating an example input device 26 including a validation process audit application 374. Input device 26 may include one or more stand-alone devices or may be part of a larger system. In certain examples, input device 26 may include a mobile device. For instance, input device 26 may include or be part of a wireless communication device (e.g., wireless mobile handset or device), a video telephone, a smart phone, an iPod, iPad, iPhone, iPod touch, a personal digital assistant (PDA), a video game console, tablet PC, a laptop computer, or other portable media players or computing devices. In some examples, input device 26 may communicate with one or more other devices via one or more networks (not shown), such as one or more wired or wireless networks, cell phone networks, the Internet, Wi-Fi, Bluetooth, Near Field Communication, Local or Wide Area Networks, or other means of electronic communication.

[0117] As shown in the example of FIG. 19, input device 26 may include one or more processors 360, one or more computer readable storage mediums 370, and a user interface 350. User interface 350 may include one or more of a display, keyboard, mouse, touchpad, track pad, touch screen, touch pad, microphone, camera, etc. Computer readable medium(s) 370 may store one or more applications 372, an operating system 380, and data storage 382. Applications 372 and operating system 380 may be executed by the one or more processors 360 included within input device 26. A user may initiate functionality of the device and input content by interacting with the user interface and/or with various other controls that may be provided by device 26. Input device 26 may also include network interface (not shown) to communicate with external devices (e.g., one or more servers, web servers, other input devices, computing devices, etc.) via one or more networks.

[0118] Computer readable medium 370 may be configured to store various types of information, software/firmware, etc., within input device 26. In some examples, computer readable medium 370 may include a temporary memory, meaning that a primary purpose of at least part of computer readable medium 370 is not long-term storage. Computer readable medium may also include volatile memory, meaning that at least a part does not maintain stored contents when the input device is turned off. Examples of volatile memories include random access memories (RAM), dynamic random access memories (DRAM), static random access memories (SRAM), and other forms of volatile memories known in the art. In some examples, computer readable medium 370 may be used to store program instructions for execution by processor(s) 360. Computer readable medium 370 may be used by software or applications running on input device 26 (e.g., one or more of applications 372 shown in FIG. 19) to store information used or generated during program execution. Computer readable medium 370 may also include non-volatile storage elements. Examples of such non-volatile storage elements may include magnetic hard discs, optical discs, floppy discs, flash memories, or forms of electrically programmable memories (EPROM) or electrically erasable and programmable (EEPROM) memories.

[0119] Each of applications 372 is operable on input device 26 to perform one or more functions during execution. For example, one or more of applications 372 may include a web application that interacts and/or exchanges data with a device that is external to input device 26. A web application may, in some instances, be executable within a web browser that is operable on input device 26. Input device 26 may, in various instances, download or otherwise obtain one or more of applications 372 from an external server via one or more networks (not shown). For instance, a web browser hosted by input device 26 may download one or more of applications 372 upon access of one or more web sites hosted by such external server (e.g., web server).

[0120] Validation process audit application 374 (which may sometimes be referred to as “validation app”) provides the functionality that permits an input device, such as input device 26, to receive validation data entered by a user during an audit/assessment of a module within a healthcare or other facility. Validation application 374, when executed by the processor, may cause one or more screens to be presented on the user interface through which a user may enter the collected data. Validation application 374 may further, when executed by the processor, cause one or more screens to be presented on the user interface through which a user may enter data concerning whether one or more high touch points were cleaned. Validation application 374 may further, when executed by the processor, cause one or more screens to be presented on the user interface through which a user may enter data concerning at least one of patient room identification information, module identification information, or unit identification information. This and other functionality of validation application 374 will be further described with respect to FIGS. 9-15.

[0121] FIG. 9 shows an example input device 400 on which an application icon 404 for a validation process audit application is displayed. The validation process audit application (for example, reference numeral 374 as shown in FIG. 19) permits data relevant to the validated hospital cleaning system to be entered into the validation system. In this example, input device 400 is a mobile phone or other mobile device that includes a display 402 on which a variety of application icons, such as application icon 404, are displayed. To start entering information, a user may tap on validation application icon 404 to open the validation process audit application.

[0122] FIGS. 10-15 show example screens that may be displayed on an input device, such as input device 400, by the validation process audit application. It shall be understood that similar screen shots may be displayed by any other type of input device, and that the disclosure is not limited in this respect.

[0123] Example screen 410, as shown in FIG. 10, permits a user to enter the module type for the data to be entered. For example, if the module within a hospital to be audited is a patient room, a user may tap the patient room icon 412A. Other modules may include, for example, observational checklist 412B, emergency room 412C, clinic/exam room
Assuming icon 412A was chosen, the application may next display a screen such as example screen 420 of FIG. 11. Screen 420 permits a user to enter the patient room number 422, the environmental services technician name or id number 424. The user may also enter whether or not the room is an isolation room using Yes/No icons 426. Screen 430 of FIG. 12 permits a user to enter a “unit name” in this example via icon 434, such as general medical/surgical, cancer care, Ob/Gyn, or any of a number of other predetermined or customized units. The unit names may be customized for each hospital or healthcare facility, or they may be predetermined. The user may select “Save” or “Done” as shown at the top right of the example screens to save the data entered at any point in the process.

Either before or after the room information is entered via screens such as those shown in FIGS. 11 and 12, a user may mark the relevant high touch points with an indicator or other suitable substance. One example of a suitable indicator is DAZO® Fluorescent Marking Gel, available from Ecolab USA Inc., St. Paul, Minn. This example marking gel is clear when applied. After cleaning, a black light inspection illuminates the gel if the surface has not been properly cleaned, thus permitting cleaning effectiveness to be audited/assessed.

The user may enter the room auditing information via example screens 440 and 450 as shown in FIGS. 13 and 14. Screens 440 and 450, in this example, display the high touch points relevant to a patient room. The user may tap “Pass” or “Fail” for each high touch point to record the results for each of the high touch points. The high touch points may include, but are not limited to, bed rail/controls 442, bedside table handle 444, call button 446, chair 448, toilet flush handle 452, toilet seat 454, as well as other relevant high touch points. When complete (all high touch points are answered with either “Pass”, “Fail”, or “NA”), the user may tap that the survey is complete using Yes/No icon 456. The user may then tap “Done/Submit” icon 458 to save the room information and/or cause the information to be wirelessly submitted to a server or other data collection point. If the input device is connected to Wi-Fi, a cell phone network, etc., a dialog box may display indicating that the data has been sent to the server. If the input device is not connected to Wi-Fi, cell phone network, etc., the data may be automatically sent the next time the device is connected.

More than one room or module may be audited at a time. The information relevant to each room/module (e.g., room number, EVS technician, room type, etc.) may be entered for each room and each room marked with the indicator. The room information will be saved on the input device. As shown in FIG. 15, an example screen 460 may display a list of rooms/modules 462A-462C. The status of the audit for each room/module may be communicated via indicators 464A (room survey is incomplete), 464B (room survey is complete and has been successfully submitted), and 464C (room survey is complete, but input device is not connected to Wi-Fi or other communications network). To enter the audit information for a room, such as Patient Room 304W, the user may tap on icon 462A to open a screen such as screen 440 shown in FIG. 13, to record the results for each high touch point.

FIGS. 16-18 show example web pages that may be generated by a reporting application, such as reporting application 34 as shown in FIG. 2A. The example web pages shown in FIGS. 16-18 may be displayed on a user computing device, such as computing device 54 as shown in FIG. 2A.

Once a user has logged in, a web page such as web page 470 as shown in FIG. 16 may be displayed. This web page may include a list of folders 472 corresponding to the room/module types (such as clinic/exam room, emergency department, lab room, patient room, etc.), a list 474 of the reports that are available for the selected room/module, along with a description 476 of what type of data is displayed in each report. To view/generate a report, the user may click or otherwise select the desired report name.

A web page 480 as shown in FIG. 18 may display input control/parameters 482 for the report to be generated. Input controls 482 may permit the user to select various report filters (e.g., quarter, year, patient area, start date, end date, etc.) related to each report. To export a report, print a report, or to use in a format in another application, the user may choose the desired format by clicking on the export drop-down description 484.

FIG. 18 shows a web page 490 that includes an example report 492. “Patient Area by Unit.” The patient area by unit chart 492 shows the total percentage of high touch objects cleaned across multiple time periods. The results are broken down by patient room, patient bathroom, and facility total. In addition, similar reports may also be run by high touch object, unit, module, environmental services technician (housekeeper), or other appropriate variable. Other reports showing benchmarking of the facility with other facilities may also be provided.

Other reports may be generated and/or presented may include an audit progress report (the number of patient rooms that should be monitored on a periodic basis (e.g., quarterly, monthly, biannually, or other periodic basis) based on the hospital bed size and provides tracking that allows the facility to view progress against the sampling plan), a focus area report (presents the top three (or other appropriate number) high touch objects that are frequently cleaned along with the bottom three (or other appropriate number) high touch objects that are frequently missed by a facility), a heat map (a color-coded visual indicator of the percentage of high touch objects cleaned within a patient room by baseline, last period, and current period), cleanliness trend by hospital report (provides a report of the facility progress against the facility sampling plan), overall cleanliness results by hospital (over cleanliness scores for the facility), etc.

A user may also schedule reports to be sent automatically. The user may choose which reports are to be generated, and how often each of these reports should be sent, and to whom.

Although certain reports are shown and/or described herein, it shall be understood that a wide variety of reports may be generated and/or displayed, and that the disclosure is not limited in this respect.

Various modules and validation processes of the validated hospital cleaning system/method described herein may include infection prevention solutions including chemistries, equipment, dispensing, packaging, effective utilization processes, validation and auditing methods and ease-of-use automation technologies. These may include, for example, high level disinfectants, patient bathing/wipe/wash, equipment draping, site prep, wound cleaning, cart washing,
floor tacky mats, patient screening/ID, patient pre-admission kits, room decontaminants, long life hard surface disinfectant, soft surface mist/vapor cleaning, ice machine conditioning, air filtration, visitor barriers/screens/kits, operating room cleaning solution, patient room cleaning solution, general instrument clean/sanitize, GI device clean/disinfect, fluid management/disposal, systems for cleaning/sanitizing, sensors/monitors/tracking devices, etc. [0136] The validated hospital cleaning system/method may incorporate tools for data utilization and process improvements such as data collection, analysis, utilization, and interpretation to achieve process improvements, behavioral changes, and outcome measures. For example, the validated hospital cleaning method may include tools and technology to gather/manage information, outcome data collection, data analysis and utilization, peer hospital comparisons, industry metrics/standards.

[0137] The validated hospital cleaning system/method may also include quality assurance, such as oversight and monitoring of labor providers to assure cleaning and disinfection quality across the hospital to reduce the spread of HAIs (hospital staff, outside provider employees, contractors, etc.). Quality control may also receive input from various automated machines, such as chemical dispensers that dispense various cleaning solutions, to ensure that the concentration of active ingredient in a disinfectant or other chemical is within certain limits, that the appropriate amounts are being dispensed, etc.

[0138] The validated hospital cleaning process may capture many demographics as well as measure the effectiveness of following of the validated cleaning process. The data may include, for example, information related to room cleanliness, patient satisfaction scores, HAI infection risks and others. The data may be used as a feed back loop to assure the system has been followed as prescribed in the validated process which has been shown to yield improved results in these three areas. The validated hospital cleaning system/process may include capturing a baseline status of the cleanliness of the room or the cleanliness of each module within a hospital or other healthcare facility.

[0139] As described herein, some parts of the validated hospital cleaning process may be computer implemented, and as such may be incorporated into computer software or hardware. For example, a computer system may collect and analyze data generated during implementation of the validation processes. A computer implemented system may analyze data to determine whether a particular validation point has been satisfied, and may perform statistical analysis on a process, module, or hospital-wide basis. This information may be stored and analyzed and reports generated to provide feedback to a facility manager or corporation. Furthermore, the analysis may be performed across multiple accounts, such as multiple accounts within a single corporation or organizational region, to compare, for example, one hospital in a corporation with other hospitals within the same corporation or to compare like modules of multiple hospitals.

[0140] The techniques described herein may be implemented in hardware, software, firmware, or any combination thereof. If implemented in software, the techniques may be realized at least in part by a computer-readable medium comprising instructions that, when executed by computer of a validated healthcare processing system cause the computer to perform one or more of the techniques of this disclosure. The computer-readable data storage medium may form part of a computer program product, which may include packaging materials. The computer-readable medium may comprise random access memory (RAM) such as synchronous dynamic random access memory (SDRAM), read-only memory (ROM), non-volatile random access memory (NVRAM), electrically erasable programmable read-only memory (EEPROM), FLASH memory, magnetic or optical data storage media, a magnetic disk or a magnetic tape, a optical disk or magneto-optic disk, CD, CD-ROM, DVD, a holographic medium, or the like. The instructions may be implemented as one or more software modules, which may be executed by themselves or in combination with other software.

[0141] The computer-readable instructions may be executed in the computer of the system by one or more processors, general purpose microprocessors, ASICs, FPGAs or other equivalent integrated or discrete logic circuitry.

[0142] The instructions and the media are not necessarily associated with any particular computer or other apparatus, but may be carried out by various general-purpose or specialized machines. The instructions may be distributed among two or more media and may be executed by two or more machines. The machines may be coupled to one another directly, or may be coupled through a network, such as a local access network (LAN), or a global network such as the Internet. Accordingly, the term "processor," as used herein may refer to any structure suitable for implementation of the techniques described herein.

[0143] The examples described herein may also be embodied as one or more devices that include logic circuitry to carry out the functions or methods as described herein. The logic circuitry may include a processor that may be programmable for a general purpose or may be dedicated, such as microcontroller, a microprocessor, a Digital Signal Processor (DSP), an Application Specific Integrated Circuit (ASIC), a field programmable gate array (FPGA), and the like.

[0144] One or more of the techniques described herein may be partially or wholly executed in software. For example, a computer-readable medium may store or otherwise comprise computer-readable instructions, i.e., program code that can be executed by a processor to carry out one or more of the techniques described above.

[0145] The validated hospital cleaning method may also incorporate healthcare worker training and continuing education, such as teaching new or ongoing skills and changing paradigms and behaviors within hospitals. These may include, for example, central sterile on-site process training/validiation/usage, compliance/procedural training, training oversight/monitoring/interventions, comprehensive training to impact outcomes, medical school and association curriculum, certification training, etc. This may include both on-site and regular refresher training, training materials and a training process created for each module to assure the healthcare providers are following the best practice process and using the proper tools and products to assure the use of the validated process will yield the outcome of a clean room or module, and possibly a reduced HAi risk.

[0146] The validated hospital cleaning system and method thus provides a comprehensive, hospital-wide cleaning and sanitation practice that addresses cleaning, disinfection sterilization and clinical solutions that may increase hospital cleanliness and may reduce the spread of HAIs. Advantages of the validated hospital cleaning system and method may be documented improvements in environmental sanitation, per-
ceptible room cleanliness, patient satisfaction scores, and HAI risk reduction and associated cost savings. Advantages may also include fewer patient deaths and patient complications due to HAI. The validated hospital cleaning system and method may also provide cost reductions through improved operational efficiencies and a reduction in health care worker errors and inconsistencies.

Although the validated hospital cleaning system and method has been described with respect to hospitals or other healthcare facilities, it shall be understood that this concept may also be applied to the cleaning and sanitation best practice in many different enterprises in which an integrated approach to cleaning and/or sanitizing a portion of a facility or an entire facility is desired. For example, the modular validated hospital cleaning system and method may be adapted for use in applications such as hotel room cleaning, education facilities, long term care, restaurants, food service, food and beverage facilities, eating areas, rest rooms, food preparation areas, cooking areas, etc.

Various examples have been described. These and other examples are within the scope of the following claims.

1. A system comprising:
   a database configured to store a plurality of cleaning process maps associated with a healthcare facility, each of the cleaning process maps including one or more parameters indicative of adherence to proper housekeeping procedures within the healthcare facility, and further including one or more monitoring procedures that define housekeeping data to be collected for each of the one or more parameters;
   at least one input device that receives the collected housekeeping data as entered by a user; and
   a computing device configured to receive the collected housekeeping data from the at least one input device;
   the database further configured to store the collected housekeeping data in association with hospital data that uniquely identifies the healthcare facility;
   the computing device further configured to analyze the collected housekeeping data with respect to the parameters and generate therefrom validation data indicative of whether the parameters were satisfied, and configured to generate one or more reports based on the analysis;
   the input device further including:
   at least one processor;
   a user interface; and
   a validation application that, when executed by the processor, causes one or more screens to be presented on the user interface through which a user may enter the collected housekeeping data, the one or more screens to be presented on the user interface including one or more screens through which a user may enter collected housekeeping data concerning whether one or more high touch points were cleaned.

2. The system of claim 1 wherein each of the cleaning process maps corresponds to a different one of a plurality of modules within the healthcare facility and defines housekeeping procedures associated with the corresponding module within the healthcare facility.

3. The system of claim 2 wherein the plurality of modules within the healthcare facility include at least one of a patient room module, a critical care module, a central sterile processing module, an operating room module, a food service module, a bathroom module, or a laundry room module.

4. The system of claim 2 wherein the plurality of modules include at least one of a patient skincare module, a wound cleansing module, or a hand hygiene module.

5. The system of claim 2 wherein at least one of the plurality of modules is associated with a physical area of the healthcare facility.

6. The system of claim 2 wherein at least one of the plurality of modules is associated with one or more functions carried out within the healthcare facility.

7. The system of claim 1 wherein the collected data concerning whether one or more high touch points were cleaned includes data concerning whether an indicator applied to one or more of the high touch points was disturbed.

8. The system of claim 7 wherein the indicator includes at least one of a photoluminescent indicator or a chemiluminescent indicator.

9. The system of claim 1 wherein the collected data concerning whether one or more high touch points were cleaned includes data concerning whether an indicator applied to one or more of the high touch points was removed.

10. The system of claim 1 wherein each of the monitoring procedures may include a definition of the monitoring procedure which may be used to determine whether the one or more parameters are satisfied.

11. The system of claim 1 wherein each of the monitoring procedures may include a description of a verification procedure which may be used to determine whether the parameters are satisfied.

12. The system of claim 11 wherein the verification procedure includes one of a titration procedure, a visual indicator procedure, a surface culture procedure, and a time-based monitoring procedure.

13. The system of claim 1 wherein each of the monitoring procedures may include a definition of the type of person who will perform the monitoring procedure.

14. The system of claim 14 wherein the type of person includes one of a hospital environmental services manager, a service technician, and housekeeping personnel.

15. The system of claim 14 wherein the type of person includes one of a hospital environmental services manager, a service technician, and housekeeping personnel.

16. The system of claim 1 wherein the parameters include a target concentration of an active ingredient for a disinfectant and a target amount of disinfectant to be delivered to a surface.

17. The system of claim 1 wherein the collected housekeeping data includes at least one of a titration result, a disinfectant chemical product concentration, and a dispensed detergent amount.

18. The system of claim 1 wherein the collected housekeeping data includes at least one of a bioluminescence reading and a chemiluminescence reading.

19. The system of claim 1 wherein the collected housekeeping data includes results of a microbiological culture.

20. A system comprising:
   a database configured to store a plurality of cleaning process maps associated with one of a plurality of healthcare facilities, each of the cleaning process maps including one or more parameters indicative of adherence to proper housekeeping procedures within the healthcare facility, and further including one or more monitoring procedures that define housekeeping data to be collected for each of the one or more parameters;
a plurality of input devices configured to receive the collected housekeeping data, each of the plurality of input devices associated with one or more of the plurality of healthcare facilities; and

a computing device configured to receive the collected housekeeping data from the plurality of input devices;

the database further configured to store the collected housekeeping data in association with hospital data that uniquely identifies the associated one of the plurality of healthcare facilities from which the collected housekeeping data was received;

the computing device further configured to analyze the collected housekeeping data with respect to the parameters and generate therefrom validation data indicative of whether the parameters were satisfied, and configured to generate one or more reports based on the analysis;

each of the plurality of input devices further including:

at least one processor;

a user interface; and

a validation application that, when executed by the processor, causes one or more screens to be presented on the user interface through which a user may enter the collected housekeeping data, the one or more screens to be presented on the user interface including one or more screens through which a user may enter collected housekeeping data concerning whether one or more high touch points were cleaned.
