BACKGROUND OF THE INVENTION

Prostaglandin D2 (PGD2) has long been associated with inflammatory and atopic conditions, specifically allergic diseases such as asthma, rhinitis, conjunctivitis and atopic dermatitis (Lewis et al. (1982) J. Immunol. 129, 1627). PGD2 belongs to a class of compounds derived from the 20-carbon fatty acid skeleton of arachidonic acid. In response to an antigen challenge, PGD2 is released in large amounts into the airway as well as to the skin during an acute allergic response. The DP receptor, which is a member of the G-protein coupled receptor (GPCR) subfamily, has long been thought to be the only receptor of PGD2. DP's role in allergic asthma has been demonstrated with DP deficient mice (Matsuoka et al. (2000) Science 287, 2013-2017). However, despite intense interest in the role of PGD2 in the inflammatory response, a direct link between DP receptor activation and PGD2-stimulated eosinophil migration has not been established (Woodward et al. (1990) Invest. Ophthalomol Vis. Sci. 31, 138-146; Woodward et al. (1993) Eur. J. Pharmacol. 230, 327-333).

More recently, another G-protein coupled receptor, referred to as "Chemoattractant Receptor-Homologous molecule expressed on T-Helper 2 cells" (CRTH2) (Nagata et al. (1999) J. Immunol. 162, 1278-1286, Hirai et al. (2001) J Exp. Med. 193, 255-261) has been identified as a receptor for PGD2 and this discovery has begun to shed light on the mechanism of action of PGD2. CRTH2, which is also referred to as DP2, GPR44 or DLIR, shows little structural similarity with the DP receptor and other prostanoid receptors. However, CRTH2 possesses similar affinity for PGD2. Among peripheral blood T lymphocytes, human CRTH2 is selectively expressed on Th2 cells and is highly expressed on cell types associated with allergic inflammation such as eosinophils, basophiles and Th2 cells. In addition, CRTH2 mediates PGD2 dependent cell migration of blood eosinophils and basophiles. Furthermore, increased numbers of circulating T cells expressing CRTH2 have been correlated with the severity of atopic dermatitis (Cosmi et al. (2000) Eur. J. Immunol. 30, 2972-2979). The interaction of CRTH2 with PGD2 plays a critical role in the allergen-induced recruitment of Th2 cells in the target tissues of allergic inflammation. Compounds that inhibit the binding of CRTH2 and PGD2 should therefore be useful for the treatment of allergic diseases.
Allergic disease, like asthma, and inflammatory dermatoses represent a major class of complex, and typically chronic, inflammatory diseases that currently affect about 10% of the population and that number appears to be increasing (Bush, R.K., Georgitis J.W., Handbook of asthma and rhinitis. 1st ed. (1997), Abingdon: Blackwell Science. 270).

Atopic dermatitis is a chronic skin disease, wherein the skin becomes extremely itchy. It accounts for 10 to 20 percent of all visits to dermatologists. The increasing incidence of allergic diseases and inflammatory dermatoses worldwide underscores the need for new therapies to effectively treat or prevent these diseases. Currently, numerous classes of pharmaceutical agents are widely used to treat these diseases, for example, antihistamines, decongestants, anticholinergics, methylxanthines, corticosteroids, and leukotriene modulators. However, the usefulness of these agents is often limited by side effects and low efficacy.

It has been reported recently that 3-sulphur-substituted indole derivatives (A) exhibit CRTH2 activity (WO 04/106302, AstraZeneca AB) and are potentially useful for the treatment of various respiratory diseases.

WO 04/096777 (Bayer Healthcare AG) relates to pyrimidine derivatives, which are useful for the treatment of diseases mediated by CRTH2.

WO 04/035543 and WO 05/102338 (Warner-Lambert Company LLC) disclose tetrahydrochinoline derivatives as CRTH2 antagonists (C), which are also described to be effective in the treatment of neuropathic pain.

Specific tetrahydrochinoline derivatives as CRTH2 modulators are also provided by WO 04/032848 (Millennium Pharmaceutical Inc.) and WO 05/007094 (Tularik Inc.). These tetrahydrochinoline derivatives are said to be useful for treating disorders associated with allergic inflammation processes.

Patent applications WO20051 15382, WO2007062678, and WO2007062773 also provides phenoxyacetic acid derivatives as ligands of CRTH2 receptors.

The compounds of the invention, together with a conventionally employed adjuvant, carrier, diluent or excipient may be placed into the form of pharmaceutical compositions and unit dosages thereof, and in such form may be employed as solids, such as tablets or filled capsules, or liquids such as solutions, suspensions, emulsions, elixirs, or capsules filled with the same, all for oral use, or in the form of sterile injectable solutions for parenteral (including subcutaneous use). Such pharmaceutical compositions and unit dosage forms thereof may comprise ingredients in conventional proportions, with or without additional active compounds or principles, and such unit dosage forms may contain any suitable effective amount of the active ingredient commensurate with the intended daily dosage range to be employed.

The compounds according to Formula (I) of the present invention are typically administered in form of a pharmaceutical composition. Such compositions can be prepared in a manner well known in the pharmaceutical art and comprise at least one active compound. Generally, the compounds of this invention are administered in a
pharmaceutically effective amount. The amount of the compound actually administered will typically be determined by a physician, in the light of the relevant circumstances, including the condition to be treated, the chosen route of administration, the actual compound administered, the age, weight, and response of the individual patient, the severity of the patient's symptoms, and the like.

The pharmaceutical compositions of these inventions can be administered by a variety of routes including oral, rectal, transdermal, subcutaneous, intravenous, intramuscular, and intranasal. The compositions for oral administration can take the form of bulk liquid solutions or suspensions, or bulk powders. More commonly, however, the compositions are presented in unit dosage forms to facilitate accurate dosing. The term "unit dosage forms" refers to physically discrete units suitable as unitary dosages for human subjects and other mammals, each unit containing a predetermined quantity of active material calculated to produce the desired therapeutic effect, in association with a suitable pharmaceutical excipient. Typical unit dosage forms include prefilled, premeasured ampoules or syringes of the liquid compositions or pills, tablets, capsules or the like in the case of solid compositions. In such compositions, the substituted methylene amide derivative according to the invention is usually a minor component (from about 0.1 to about 50% by weight or preferably from about 1 to about 40% by weight) with the remainder being various vehicles or carriers and processing aids helpful for forming the desired dosing form.

Liquid forms suitable for oral administration may include a suitable aqueous or non-aqueous vehicle with buffers, suspending and dispensing agents, colorants, flavors and the like. Solid forms may include, for example, any of the following ingredients, or compounds of a similar nature: a binder such as microcrystalline cellulose, gum tragacanth or gelatine; an excipient such as starch or lactose, a disintegrating agent such as alginic acid, Primogel, or corn starch; a lubricant such as magnesium stearate; a glidant such as colloidal silicon dioxide; a sweetening agent such as sucrose or saccharin; or a flavoring agent such as pepper-mint, methyl salicylate, or orange flavoring.

Injectable compositions are typically based upon injectable sterile saline or phosphate buffered saline or other injectable carriers known in the art. As above mentioned, substituted methylene amide derivatives of Formula (I) in such compositions is typically a minor component, frequently ranging between 0.05 to 10% by weight with the remainder being the injectable carrier and the like.
The above-described components for orally administered or injectable compositions are merely representative. Further materials as well as processing techniques and the like are set out in Part 5 of Remington's Pharmaceutical Sciences, 20th Edition, 2000, Marck Publishing Company, Easton, Pennsylvania, which is incorporated herein be reference.

The compounds of this invention can also be administered in sustained release forms or from sustained release drug delivery systems. A description of representative sustained release materials can also be found in the incorporated materials in Remington's Pharmaceutical Sciences.

The compounds according to formula (I) can be prepared from readily available starting materials using the following general methods and procedures. It will be appreciated that where typical or preferred experimental conditions (i.e. reaction temperatures, time, moles of reagents, solvents etc.) are given, other experimental conditions can also be used unless otherwise stated. Optimum reaction conditions may vary with the particular reactants or solvents used, but such conditions can be determined by the person skilled in the art, using routine optimisation procedures.

O-PG" denotes a protecting group, preferably for acyl groups, i.e. an acyl-protecting group. O-PG denotes preferably an O-alkyl group like tert-butoxy, methoxyl, ethoxy or benzyloxy group.

The term "protecting group" is known in general terms and relates to groups which are suitable for protecting a functional group against chemical reactions, but are easy to remove after the desired chemical reaction has been carried out elsewhere in the molecule. The nature and size of the protecting groups are not crucial since they are removed again after the desired chemical reaction or reaction sequence; preference is given to groups having 1-20, in particular 1-10, carbon atoms.

In general, compounds according to Formula (I) of this invention can be prepared from readily available starting materials. If such starting materials are not commercially available they can be prepared by standard synthetic techniques. The following general methods and procedures described hereinafter in the examples can be employed to prepare compounds of Formula (I).

Depending on the nature of R¹, R², R³, Q, m and n in formula (I), different synthetic strategies may be selected for the synthesis of compounds of Formula (I). In the process illustrated in the following schemes R¹, R², R³, Q, X, m and n are as defined in the description.

Generally, compounds of Formula (I), wherein R¹, R², R³, Z, Q, m and n are defined as above, can be obtained in 2 steps as outlined in Scheme 1. The first step consists in coupling a compound of Formula (II), wherein R¹, R², R³, Z, Q, m and n are defined as above, X denotes Cl, Br, preferably Br or I, or trifluoromethanesulfonyl and wherein PG denotes a protecting group such as tert-butyl, with an alkyne of Formula (III), wherein Q
is defined as above. General protocols for such coupling are given below in the Examples, using conditions and methods well known to those skilled in the art to perform such coupling. The reaction can optionally be performed with an appropriate catalyst such as but not limited to dichlorobis(triphenylphosphine)palladium(II) or 1,1'-bis(diphenylphosphino)ferrocenedichloro palladium(II), Pd(OAc)$_2$, Pd$_2$(dba)$_3$, or Pd/C in the presence or absence of an additional ligand, such as but not limited to P(Ph$_3$)$_3$, P(OTol)$_3$, PPh$_3$, BINAP. Additionally, the reaction can optionally be performed in the presence of a suitable copper salt such as but not limited to copper (I) iodide, copper (I) bromide or copper (I) chloride. The reaction can be performed in the presence or absence of bases such as TEA, DIEA, NMM, piperidine, Cs$_2$CO$_3$, sodium phosphate, in the presence or absence of a suitable solvent such as THF, ACN, DMF, acetone at a temperature between about 20 °C to about 100 °C, preferably at about 70 °C, for a few hours, e.g. one hour to 24 h. For a list of conditions described for the coupling of an aryl alkyne with an aryl or heteroaryl triflate or halide, see also Rafael Chinchilla and Carmen Najera, Chem. Rev. 2007, 107, 874-892.

Conversion of compounds of Formula (IV) to give compounds of Formula (I) can be achieved using conditions and methods well known to those skilled in the art for the conversion of an ester to a carboxylic acid, such as but not limited to treatment with a base or an appropriate acid, such as trifluoroacetic acid or hydrochloric acid, in the presence of a suitable solvent such as DCM, dioxane, THF at a temperature between about 20 °C to about 100 °C, preferably at about 20 °C, for a few hours, e.g. one hour to 24 h.

Scheme 1
Compounds of Formula (II), wherein R₁', Rₓ, Rᵧ, Z, X, PG, m and n are defined as above, can be prepared by alkylation of a compound of Formula (V), wherein R¹, Z and X are defined as above, with a compound of Formula (VI), wherein Rₓ, Rᵧ, X, PG, m and n are as defined above, as outlined in Scheme 2. The reaction can be performed in the presence of a suitable base, such as potassium carbonate, sodium carbonate, sodium hydroxide, potassium hydroxide, sodium tert-butoxide, in the presence of a suitable solvent such as DCM, dioxane, THF, in the presence or absence of water. The reaction can be carried out at a temperature between about 20 °C to about 100 °C, preferably at about 20 °C, for a few hours, e.g. one hour to 24 h. Alternatively, the Compounds of Formula (II) can be prepared by reaction of a compound of Formula (V) with an opportunely protected hydroxyalkyl carboxylic acid under Mitsunobu conditions, using conditions and methods well known to those skilled in the art such as in the presence of a phosphine, such as but not limited to triphenylphosphine, and an azadicarboxylate, such as but not limited to diisopropylazadicarboxylate.

Scheme 2
Compounds of Formula (IV) wherein Q, Z, R₁, Rₓ, Rᵧ, PG, m and n are as above defined can be obtained by coupling a compound of Formula (VII) wherein Z, R₁, Rₓ, Rᵧ, PG, m and n are as above defined, with a compound of Formula (VIII) wherein Q is as above defined and wherein X denotes a triflate or an halide, preferably a bromide or an iodide, as outlined in Scheme 3. General protocols for such coupling are given below in the Examples, using conditions and methods well known to those skilled in the art to perform such coupling. This reaction is preferably performed with an appropriate catalyst such as but not limited to dichlorobis(triphenylphosphine)palladium(II) or 1,1'-bis(diphenylphosphino)ferrocenedichloro palladium(II), Pd(OAc)₂, Pd₂(dba)₃, Pd(Cl)₂ or Pd/C in the presence or absence of an additional ligand, such as but not limited to P(^Bu)₃, P(OToI)₃, PPh₃, BINAP. The reaction can also be performed in the presence of a suitable copper salt such as but not limited to copper (I) iodide, copper (I) bromide or copper (I) chloride. The reaction can be performed in the presence or absence of bases such as TEA, DIEA, NMM, piperidine, Cs₂CO₃, sodium phosphate, in the presence or absence of a suitable solvent such as THF, ACN, DMF or acetone. This coupling reaction can be carried out at a temperature between about 20 °C to about 100 °C, preferably at about 70 °C, for a few hours, e.g. one hour to 24 h.

Intermediate 138: 3-bromo-4-fluoro-$\Lambda,\Lambda$-dimethylbenzenesulfonamide

Step 1: 4-fluoro-$\Lambda,\Lambda$-dimethylbenzenesulfonamide

A cooled (0 °C) solution of 4-fluorobenzenesulfonyl chloride (2.00 g; 10.3 mmol) in THF (40 ml) is treated with a 2 M solution of dimethylamine in THF (11.3 ml; 22.6 mmol) and stirred at 0 °C for 30 minutes. The solvents were removed under reduced pressure, the residue taken up in EtOAc, the organic phase was washed with a saturated solution of NH$_4$Cl twice and with water. The organic phase was dried on MgSO$_4$, filtered and the solvent removed under reduced pressure to afford the title compound (1.80 g, 86%).

Step 2: 3-bromo-4-fluoro-$\Lambda,\Lambda$-dimethylbenzenesulfonamide
A solution of 4-fluoro-\(\Lambda,\Lambda\)-dimethylbenzenesulfonamide (1.80 g; 8.86 mmol) in cone. sulfuric acid (7 ml; 130 mmol) was treated with \(\Lambda\)-bromosuccinimide (1 730 mg; 9.74 mmol) and stirred at RT for 3 h. The reaction mixture was carefully poured on crushed ice, extracted with AcOEt and the organic phase was washed with a 0.1 N solution of NaOH in water twice, then with brine twice. The organic phase was dried on MgSO\(_4\), filtered and concentrated under reduced pressure to give the title compound as a white solid (2.04 g, 82%).

\(^1\)H NMR (300MHz, DMSO-\(d_6\)) \(\delta\) [ppm] 8.04 (1H, dd, \(J= 6.5\) Hz, \(J= 2.2\) Hz), 7.83 (1H, ddd, \(J= 8.7\) Hz, \(J= 4.6\) Hz, \(J= 2.3\) Hz), 7.66 (1H, t, \(J= 8.7\) Hz), 2.65 (6H, s).

The compounds in the table below were all prepared following the general method as outlined in Intermediate 138:

Example 175: Radioligand binding assay

The compounds of the present invention inhibit the binding of PGD2 to its receptor CRTH2. The inhibitory activity can be investigated by a radioligand binding Scintillation Proximity Assay (SPA) (Sawyer et al., Br. J. Pharmocol 2002, 137, 1163-72). The SPA radioligand binding assay was performed at room temperature in binding buffer (10 mM HEPES/KOH pH 7.4, 10 mM MnCl₂, with protease inhibitor cocktail tablets), containing 1.5 nM [³H]PGD₂ (Perkin Elmer), 10-50 µg/ml of hCRTH2-CHO cell membrane protein and 2 mg/ml of Wheat-germ agglutinin Scintillation Proximity Assay beads (RPNQ0001, GE-Healthcare) in a final volume of 100 µl in 96 well plates (Corning, USA). Non-specific binding was determined in the presence of 10 µM PGD₂ (Cayman, USA). Competing Compounds of Formula (I) were diluted in dimethylsulphoxide so that the total volume of dimethylsulfoxide was kept constant at 1% dimethylsulphoxide (Me₂SO). Serial dilutions of 100 µM to 100 pM were prepared and 10 µl each of the compounds of Formula (I) stock solutions were added to the binding assay reagents and incubated for 90 min with agitation at room temperature. Binding activity was determined by using a 1450 Micro-beta scintillation counter (Wallac, UK).
In one embodiment, the compounds of Formula (I) of the present invention inhibit CRTH2 at a concentration of <5 µM. In another embodiment, the compounds of Formula (I) of the present invention inhibit CRTH2 at a concentration of <1 µM. In a preferred embodiment, the compounds of Formula (I) of the present invention inhibit CRTH2 at a concentration of <0.1 µM.

The $^{35}$S]GTPyS assay measures the increase in guanine nucleotide exchange at G-proteins in cell membranes, resulting from agonist (PGD2) binding to CRTH2. This process can be monitored in vitro by incubating cell membranes containing G-proteins and CRTH2 with GDP and $^{35}$S]GTPyS, a radiolabeled, hydrolysis-resistant analogue of GTP (see, Harrison et al., Life Sciences 74, 489-508, 2003). The addition of agonist binding, which can be monitored as inhibition of the stimulation of GTP/GDP exchange.

Briefly, Compounds of Formula (I) are incubated in 96-well scintillating white polystyrene plates (Perkin Elmer, USA) in a final volume of 200 µl containing 20mM HEPES/KOH pH 7.4, 3mM MgCl$_2$, 10 µg/ml Saponin, 5µM GDP, 75 mM NaCl and 2% of dimethylsulphoxide (DMSO). Reaction is triggered by the addition of 5-1 µg of CHO-CRTH2 cell membranes and 0.15 nM $^{35}$S]GTPyS. After 60 min incubation at 30°C, reaction is stopped by centrifugation at 700 x g, at 4°C for 10 minutes and supernatant is removed. The radioactivity coming from the $^{35}$S]GTPyS bound on centrifuged cell membranes is recorded using a 1450 Micro-beta scintillation counter. For IC$_{50}$ determination, increasing concentrations of compounds are incubated in presence of a fixed concentration of PGD2 (EC$_{50}$). For EC$_{50}$ measurements, compounds are incubated without addition of PGD2. Basal $^{35}$S]GTPyS activity is determined without addition of any ligands or compounds. 100% $^{35}$S]GTPyS activity is measured by the addition of 1µM of PGD2.

In one embodiment, the compounds of Formula (I) of the present invention are antagonists of CRTH2. The results of selected examples are reported in the Table below.

**Example 177: Cellular Dielectric Spectroscopy**

Cellular Dielectric Spectroscopy (CDS) is a label-free technology based on the measurement of complex impedance changes (delta Z or dZ). Impedance (Z) is related to the ratio of voltage to current as described by Ohm's law (Z = V/I). In order to measure the changes in impedance that occur in response to receptor stimulation, mammalian cells are seeded onto a custom 96-well microtiter plate that contains electrodes at the bottom of each well. Key contributors to the impedance measurements are changes in cell-substrate adherence, changes in cell shape and volume, and changes in cell-cell interactions. These factors individually or collectively affect the flow of current, influencing the magnitude and characteristics of the signal measured. G-protein coupled
receptors ligand-induced activity can be measured using this technology and specific G protein coupling can be identified. Activities of reference agonist and antagonist molecules of CRTH2 have been measured using this assay and similar results were obtained compared to different functional assays.

CHO-CRTH2 cells are cultured in HAM's F12 (Lonza, Switzerland) supplemented with 10% foetal calf serum (PAA, Australia) and 400 µg/ml Geneticin. 100,000 cells/well are seeded in standard 96W Microplates (MDS Analytical Technologies) and incubated at 37°C in 5% CO₂ for 24 hours. Cells are washed twice with 135 µl of cell key buffer (Hank's Balanced Salt Solution 1X (HBSS) (Invitrogen) supplemented with 10 mM HEPES pH 7.4 in presence of 1% DMSO). For EC₅₀ determination, 15 µl of increasing concentration of Compounds of Formula (I) diluted in cell key buffer are added to the cells and agonist activity is then recorded for 25 minutes. For IC₅₀ determination, 16.6 µl of a fixed concentration of PGD₂ (EC80) diluted in cell key buffer is added to the cells-compounds mixture, and antagonist activity is measured during 25 minutes. Results are expressed as the amplitude between the highest and the lowest signal produced (max-min). Basal and maximum activities are measured, respectively in absence or presence of PGD₂ (EC₈₀).

Example 178: PGD2-induced Eosinophil Cell Shape assay in Human Whole Blood

The Compounds of Formula (I) were diluted in dimethylsulphoxide so that the total volume of dimethylsulfoxide was kept constant at 2% dimethylsulphoxide (Me<sub>2</sub>SO). Serial dilutions of 200 µM to 0.09 µM were prepared. Samples of 90 µl of human blood from healthy volunteers (Centre de Transfusion Sanguine de Geneve) were pre-incubated in polypropylene Falcon tubes (BD 352063) for 20 minutes in a water bath at 37 °C with 10 µl of diluted compounds. For CRTH2 activation, 100 µl PGD2 (Cayman 12010) at 20 nM was added (10 nM final) to each tube and cells were maintained at 37 °C. For negative control cells were treated with PBS. After 10 minutes, cell activation was stopped with 120 µl Formaldehyde 10% (4% final, Fluka 41650) and cells were rested for 10 minutes at room temperature. Fixed cells were transferred into polypropylene tubes and then treated for 1 hour in a water bath at 37 °C with 2ml of Triton - Surfact-Amps X-100 (Pierce 28314) at 0.166% (0.13% Triton final). After several washes with PBS (red cells lysed progressively during washes, two washes are necessary), cells were analyzed by flow cytometry on a FACSCalibur. In one embodiment, the compounds of Formula (I) of the present invention are capable of blocking the cell shape change of eosinophils induced by PGD2 in Whole Blood. The results of representative examples are reported in the Table below.

**Example 179: In vivo Pharmacokinetic Evaluation in Rat and Mouse.**

In order to study the pharmacokinetic (PK) profile of test compounds in vivo, Sprague Dawley male rats or C57BL/6 female mice were dosed intravenously or after oral gavage. For both species, test compounds were dosed in solution at 1 mg/kg for i.v. route (10% ethanol, 10% N, N-dimethylacetamide, 30% propylene glycol, 50% water, v/v) and in suspension at 5 mg/kg (0.5% carboxymethylcellulose suspension, containing 0.25% Tween 20 in water) for oral gavage. PK profile in rat was obtained from 3 animals per dosing route and mouse PK profile was determined from 3 animals for each time points. The volume of administration was 2 mL/kg for i.v. dosing in both species and either 5 mL/kg (rat) or 10 mL/kg (mouse) for oral gavage. Blood samples (100 µL/time point) were collected at 0.083 (5 min), 0.25, 0.5, 1, 4, 7 and 24 hours post-dose for i.v. dosing, and at 0.5, 1, 4, 7 and 24 h for oral dosing, into heparin-Li+ containing tubes. For rats, all blood samples were collected through a catheter in the carotid artery (placed in the artery the day before the experiment), under light isoflurane anesthesia, and stored on ice until centrifugation and plasma isolation. For mouse, blood samples were collected from intracardiac puncture at sacrifice at each time point and processed as described above for the rat. Plasma samples were stored frozen until analysis (-20 °C to -70 °C). For bioanalysis, samples were processed by protein precipitation (acetonitrile, formic acid 0.1%, addition of 3 volumes) after addition of one internal standard and

Example 180: OVA-induced lung eosinophilia in mice
BALB/c mice (6 - 8 weeks old) were immunized with ovalbumin (10 µg i.p) on day 0 and 7. In order to elicit a local inflammatory response in the lung, mice were challenged between day's 15 - 17 with a nebulised solution of ovalbumin (10 µg/ml; De Vilibiss
Ultraneb 2000, once daily for 30 min during the 3 days). On each separate day between 15 and 17 each animal received via oral gavage the test compound, at t -1 h and t +7 h with respect to OVA exposure at t =0 h. Eight hours after the final OVA challenge, bronchoalveolar lavage (BAL) was then carried out. Total cell numbers in the BAL fluid samples were measured using a haemocytometer. Cytospin smears of the BAL fluid samples were prepared by centrifugation at 1200 rpm for 2 min at room temperature and stained using a DiffQuik stain system (Dade Behring) for differential cell counts. Compounds of Formula (I) of the present invention were tested at 3, 10 and 30 mg/Kg. Selected compounds showed a significant decrease of cell numbers in BALF. Example 181: FITC 1 week model

Fluorescein isothiocyanate (FITC) induced contact hypersensitivity (CHS) is a commonly used model for atopic dermatitis (AD). The hapten FITC is a small molecule that is able to elicit an immune response only when attached to a larger carrier such as a protein. It is reactive towards e-amino groups (lysine). The immune response to FITC sensitization and challenge is Th2 cytokine driven (IL-4, IL-5, IL-6, IL-10 and IL-13) and associated with elevated serum IgE levels. The skin inflammation at the site of the challenge is characterized by edema and eosinophil infiltrations.
Female 9 week old Balb/C mice were sensitized on days 0 and 1 with 0.5% FITC in acetone/dibutylphthalate (A/DBP). One group (sham) was sensitized with A/DBP alone. On day 6 all the mice including the sham group were challenged on the right ear (inner and outer surface) with 0.5% FITC in A/DBP. The mice were treated with the compounds via oral gavage 1 h before and 7 h after the challenge. The baseline ear thickness was measured before the challenge and 24 h after the challenge. At the end of the experiment (24 h after the challenge) the mice were sacrificed. Serum and plasma samples were taken. The challenged ear was excised and stored at -80 °C. Compounds of Formula (I) of the present invention were tested at 3, 10 and 30 mg/Kg. Selected compounds showed a significative decrease of ear swelling. For example the compounds of Examples 38, 89 and 154 showed the % inhibition of ear swelling as showed in the table below.
