There are provided immunogenically active fractions of the tick-borne spirochaetes Borrelia burgdorferi, comprising antigenic polypeptides, proteins, glycolipids and carbohydrates, and processes for their preparation. The fractions are useful in preparing vaccines for immunizing mammals against Lyme disease and related disorders.

2001328

ABSTRACT OF THE DISCLOSURE

There are provided immunogenically active fractions of the tick-borne spirochaetes Borrelia burgdorferi, comprising antigenic polypeptides, proteins, glycolipids and carbohydrates, and processes for their preparation. The fractions are useful in preparing vaccines for immunizing mammals against Lyme disease and related disorders.

FIELD OF THE INVENTION

5 The present invention relates to immunogenically active fractions of *Borrelia burgdorferi* spirochaetes comprising antigenic polypeptides, proteins, glycolipids and carbohydrates useful for immunization against and diagnosis of Lyme disease, a method of preparing the immunogenically active fractions, a vaccine comprising an immunogenically effective amount of one or several of the immunologically active fractions or a part thereof, a diagnostic agent
10 comprising one or several of the immunogenically active fractions or a part thereof, a DNA fragment encoding an antigenic polypeptide related to the outer membrane protein OspA present in the immunogenically active fractions, a monoclonal or polyclonal antibody directed against one or several of the immunogenically active fractions or antigenic polypeptide, and the use of
15 the fractions, polypeptide or antibody for diagnostic and therapeutic purposes.

Lyme disease is a zoonosis caused by the tick-borne spirochaete *B. burgdorferi* (1). When a susceptible host is bitten by an ixodid tick, *B. burgdorferi* organisms enter the skin. In humans the initial skin manifestation
20 is termed erythema chronicum migrans (ECM) whereas a long-standing infection of the skin produces acrodermatitis chronica atrophicans (2). The *Borrelia* organisms also enter the circulatory system of the host and are distributed to various organs, including the brain and joints (3). A secondary spread of the pathogens produces a variety of clinical syndromes, including
25 lymphocytic meningoradiculitis (4), myocarditis (5) and chronic arthritis (6). In many patients the infection of some tissues, particularly the brain and joints, persists for years and can be severely disabling. These forms of chronic Lyme disease are a consequence of the host's inability to rid itself of the infectious agent and perhaps the development of an autoimmune reaction (7).

30

Diagnosis of Lyme disease has chiefly been based on clinical evidence. The best marker during the primary stage of infection has been the presence of erythema chronicum migrans (ECM) but these skin le-

sions may not always develop or they may manifest atypically (7). Moreover, Lyme disease can be confused with other illnesses characterized by neurologic or arthritic manifestations. When clinical histories are incomplete, serologic testing with determination of antibody titers is the best laboratory method of diagnosis. Indirect fluorescent antibody (IFC) staining tests and enzyme-linked immunosorbent assays (ELISA) are used to detect total immunoglobulins (8) or class-specific IgM and IgG antibodies to *B. burgdorferi* (9). ELISA is usually preferred because the procedures are more easily standardized and automated and because absorbance values can be statistically analyzed to give more objective results (8).

B. burgdorferi spirochaetes are helically shaped, motile cells with an outer cell membrane that surrounds a protoplasmic cylinder complex, consisting of the cytoplasm, the cell wall, the inner cell membrane and the flagella which are located not at the cell surface but in the periplasmic space between the outer cell membrane and the protoplasmic cylinder. The outer cell membrane and the flagella are assumed to play an important role in the host-parasite interactions during the disease and has been subjected to several investigations, identifying major surface-exposed proteins as important immunogens (11).

It has been shown that the earliest IgM antibodies formed against antigens of the *B. burgdorferi* strain B31, which was deposited in the American Type Culture Collection in 1983 with the accession number ATCC 35210, are directed against a genus-specific flagellar polypeptide termed flagellin having a molecular weight of 41 kd (10) and which reacts with monoclonal antibody H9724 (22). IgG antibodies are also first directed to the 41 kd flagellin, but with advancing disease IgG antibodies form against other immunogens, especially against two abundant proteins with molecular weights of 31 kd and 34 kd. These two proteins, which have been denoted OspA (31 kd) and OspB (34 kd), have been found to be located at the *B. burgdorferi* surface and embedded in its outer fluid cell membrane (11). The OspA protein has been found to be less variable in its molecular weight and in its reactivity with monoclonal antibody H5332 (12), whereas the molecular weight of OspB proteins from different *B. burgdorferi*

strains vary and the OspB proteins of different strains also show varying reactivity with two monoclonal antibodies against OspB (H6831 and H5TS (13). The main variation among OspA proteins is found between isolates from Europe and the United States.

5 Conventional diagnostic tests for Lyme disease have used whole spirochaetal sonic extracts as test antigens in ELISA to detect antibodies to *B. burgdorferi*, but this test yields unsatisfactory low diagnostic sensitivity (20 to 60%) during the early stage of infection (14), possibly due to a slow and late-appearing antibody response and to
10 the inclusion of irrelevant cross-reacting antigens in the whole-cell preparations. In addition, the use of whole cells as test antigens may result in the occurrence of false positive reactions. For example, among patients with syphilis and in areas where a closely related relapsing fever *Borrelia* spp. co-exist with *B. burgdorferi*,
15 serologic differentiation of Lyme disease from tick-borne relapsing fever is difficult (15). Detection of IgG antibody to *B. burgdorferi* in later stages of infection can help in distinguishing Lyme disease from aseptic meningitis, multiple sclerosis, serum negative rheumatoid arthritis, juvenile rheumatoid arthritis, and Reiter's syndrome
20 (9).

Several researchers have focused on isolating flagellin or preparing flagellin-enriched whole cell or fractions for diagnostic agents so as to improve diagnostic tests for an early diagnosis of Lyme disease. For this purpose, Coleman et al. (15) have obtained *B. burgdorferi* fractions by treating whole spirochaetes with the denaturing detergent sodium dodecyl sulfate (SDS) so as to obtain a pro-
25 toplasmic cylinder flagellar (PC) fraction which upon subsequent shearing, filtration and dialysis constituted a flagellin-enriched fraction from which immunogenic polypeptides (flagellin) were eluted
30 and used as antigens in ELISA for IgG and IgM antibodies. The flagellin-enriched fraction was reported to be a useful antigen for early stage reactivity. Also, Grodzicki et al. (58) discloses fractions of *B. burgdorferi* containing flagellin.

Hansen et al. (16) describes a method of preparing purified prepara-

tion of flagella usable as an antigen in an ELISA analysis for IgM antibody detection.

US 4,721,617 discloses the use of inactivated whole *B. burgdorferi* spirochaetes as a vaccine against Lyme disease and broadly teaches
5 the concept of using an outer envelope fraction or its component polypeptides in vaccines but does not distinguish or give guidance as to which components to select for this purpose.

EP 252 641 discloses the use of antibodies specific to one or more antigens of *B. burgdorferi*, e.g. related to the cell wall or cell
10 membrane of the organism. OspA and OspB are mentioned as examples of such antigens and fractions of *B. burgdorferi* are mentioned in general. The antibodies are stated to be useful in detecting *B. burgdorferi* antigens in urine and in diagnosing Lyme disease.

As explained above, the enzyme-linked immunosorbent assays for the
15 diagnosis of Lyme borreliosis have been based on whole cell preparations. Such ELISA methods have shown good sensitivity, but lacked specificity (8, 9 and 59). Other antigenic preparations have been used such as the flagellin and fractionated antigens containing flagellin (15 and 58). These tests have showed a sensitivity almost
20 as good as the test based on whole cell antigens, and greater specificity. However, these latter tests have proved most useful in the diagnosis of early stages of Lyme disease. Flagellin or fractions containing flagellin has been shown to be less suitable for use in the diagnosis of later stages of Lyme disease, because of a low
25 specificity, i.e. a high cross-reactivity with antibodies raised in connection with other related diseases. The specificity of an assay for *B. burgdorferi* antibodies of various stages of Lyme disease, in which assay flagellin or a flagellin-enriched fraction is used, could be too low to be generally usable. Thus, there is a need for developing an assay for use in the diagnosis of various stages of Lyme
30 disease which assay has a high sensitivity and specificity for *B. burgdorferi* antigens.

Furthermore, it would be desirable to provide individuals such as humans and animals with a broad protection against Lyme disease by

means of immunization.

SUMMARY OF THE INVENTION

5

The present invention discloses easily extracted immunologically active *B. burgdorferi* fractions that increase the specificity of assays for *B. burgdorferi* antibody and are potential vaccine components and useful in antibody tests for the immunization and diagnosis of Lyme disease.

10

In accordance with one embodiment, the invention provides an immunologically active fraction B of *Borrelia burgdorferi* obtainable by the following steps:

- 15 a) lysing *B. burgdorferi* spirochaete cells with a mild nondenaturing detergent so as to release outer membrane components from the cells in a non-denatured form, and subsequently subjecting the lysed cells to centrifugation resulting in a first pellet comprising cell wall and flagellar components and a first supernatant comprising outer membrane components,
- 20
- b) incubating the first supernatant from step a) at 56°C for 30 minutes followed by centrifugation so as to obtain a second pellet comprising fraction E and a second supernatant,
- 25
- c) subjecting the second supernatant from step b) to filtration and dialyzing the supernatant against an aqueous medium with a low ionic strength or subjecting the supernatant to ultrafiltration so as to substantially remove the mild non-denaturing detergent and complex *B. burgdorferi* derived cell components in the dialysis bag or in the filtrate resulting from the ultrafiltration,
- 30
- d) centrifugating the contents of the dialysis bag so as to obtain a third pellet comprising fraction B and a third supernatant comprising fraction C,
- 35

5a

the fraction B being substantially free from cell wall and flagellar components of *B. burgdorferi*, being substantially free from sodium dodecyl sulfate

- 5 and reacts with at least about 85% of sera from patients with Lyme disease, but with not more than about 20% of sera of syphilitic patients.

In accordance with a further embodiment, the invention provides a vaccine for immunizing a mammal, including a human being, against Lyme disease and
10 related disorders, the vaccine containing an immunologically effective amount of substantially pure OspA polypeptide of *Borrelia burgdorferi* or of a part thereof, in admixture with an immunologically acceptable carrier or vehicle.

In accordance with a further embodiment, the invention provides a vaccine for
15 immunizing a mammal, including a human being, against Lyme disease and related disorders, the vaccine containing an immunologically effective amount of at least one OspA polypeptide or a part thereof, where the polypeptide or part thereof is free from other *B. burgdorferi* spirochaete related material.

20 In accordance with a further embodiment, the invention provides for the use of an immunogenically effective amount of a substantially pure OspA polypeptide of *B. burgdorferi* or a part thereof in the preparation of a composition for the immunization against Lyme disease and related disorders in a mammal, including a human being.

25

In accordance with a further embodiment, the invention provides for the use of an immunologically effective amount of a substantially pure OspA polypeptide of *B. burgdorferi* or a part thereof for the immunization of a mammal, including a human being, against Lyme disease and related disorders.

30

DETAILED DESCRIPTION OF THE INVENTION

The present invention relates to immunologically active fractions B, C and E of
35 *B. burgdorferi* obtained by the following steps:

5b

- 5 a) lysing *B. burgdorferi* spirochaete cells with a mild non-denaturing detergent so as to release outer membrane and cytoplasmic components from the cells, and subsequently subjecting the lysed cells to centrifugation resulting in a first pellet comprising cell wall and flagellar components and a first supernatant comprising outer membrane and cytoplasmic components,
- 10 b) incubating the first supernatant from step a) under conditions sufficient to precipitate at least part of the proteins of the first supernatant followed by centrifugation so as to obtain a second pellet comprising fraction E and a second supernatant,
- 15 c) subjecting the second supernatant from step b) to filtration and dialyzing the supernatant against an aqueous medium with a low ionic strength or subjecting the supernatant to ultrafiltration so as to substantially remove the mild non-denaturing detergent and allow *B. burgdorferi* derived cell components to precipitate in the dialysis bag or in the filtrate resulting from the ultrafiltration,
- 20 d) centrifugating the contents of the dialysis bag or the filtrate resulting from the ultrafiltration so as to obtain a third pellet comprising fraction B and a third supernatant comprising fraction C.
- 25 From the above general explanation of the background of the invention it is evident that efforts have been focused on isolating antigens or

fractions of *B. burgdorferi* which are useful in diagnosing Lyme disease. Various techniques for preparing fractions have been employed, most of them aiming at obtaining fractions containing flagellin. The fractions of the invention obtained by the above explained steps may seem to be similar to previously described fractions of *B. burgdorferi*. However, the composition of the fractions obtained by these steps, which composition is discussed in further detail below, has been shown to provide a specificity and a sensitivity in the diagnosis of Lyme disease which is greater than the specificities and sensitivities obtained before. This is explained in Example 1 and 5 hereinafter. Furthermore, in these examples it is shown that early as well as late stages of the disease may be diagnosed with a high specificity.

Fractions B, C and E of the present invention are novel. The method outlined above by which the fractions of the invention may be obtained involves several steps, which will be described in details below. One step in the method of obtaining the fractions of *B. burgdorferi* is the initial lysis of the *B. burgdorferi* spirochaetes. The lysis is performed under conditions which ensure that the outer membrane and the components attached thereto are substantially released from the cell wall and flagellar components whereby fractions of important antigenic components, which are valuable for late stage detection of Lyme disease, are obtained. These conditions may be fulfilled by use of a mild non-denaturing detergent which, as will be described below, is preferably a non-denaturing, water-dialysable lysating agent such as a non-ionic, zwitterionic or anionic detergent, e.g. octyl- β -D-glucopyranoside (OGP). Since the fractions of the invention are substantially free from flagellar proteins, there is minimal cross-reactivity with antibodies directed against flagella from other bacteria.

In the present context, the term "immunologically active fractions" is intended to mean parts or subunits of *B. burgdorferi* spirochaetes that give rise to an immune response and/or elicit antibodies which are reactive with *B. burgdorferi* antigens. The term "fractions" is used interchangeably with "immunologically active fractions". Fractions B, C and E contain a number of components or substances related

to the outer membrane such as major surface polypeptides as well as non-protein components such as lipids, glycolipids and carbohydrates. These components may also show immunological activity.

By the term "flagellar components" is meant components or substances being part of the flagella or closely associated with the flagella. Especially, the term "flagellar components" covers the immunogenic substances which are responsible for the cross-reactivity with antibodies directed against other bacteria, e.g. the protein, flagellin, or an antigenic part thereof from *Borrelia* species.

10 In another aspect, the present invention relates to immunologically active fractions B, C and E of *B. burgdorferi* spirochaetes, each fraction being characterized by a protein distribution pattern resulting from sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) under the conditions specified in Example 1 being
15 substantially similar to the protein distribution pattern shown in Fig. 2, which protein distribution pattern is the pattern obtained from SDS-PAGE analysis of fractions B, C and E of *B. burgdorferi* spirochaetes of New York strain B31 (ATCC 35210) isolated from the tick *Ixodes dammini*, the SDS-PAGE analysis being performed as described in Example 1.
20

As will be more specifically illustrated in the following, *B. burgdorferi* strains of different geographical origin differ in their protein profiles. Thus, the proteins contained in fractions B, C and E of different strains of *B. burgdorferi* do not have exactly the same
25 molecular weight as determined by SDS-PAGE analysis. Furthermore, certain proteins identified in fractions B, C and E may be found in some *B. burgdorferi* strains but may be absent in other strains. The immunological activity of the fractions B, C and E are, however, believed to be conserved in the different strains, and the proteins
30 of similar type, e.g. the OspA protein from the *B. burgdorferi* strain B31 (ATCC 35210) and the OspA protein from the *B. burgdorferi* strain ACA-1 (18), are believed to have substantially the same immunological properties and have in fact been shown to react similarly with antibodies raised against the proteins. Thus, the immunological activity
35 of fractions B, C and E is (at least partly) believed to be due to

the presence of a certain mixture of proteins, which will be discussed in further detail in the following. However, also non-proteinaceous components such as carbohydrates, lipids, glycolipids or phospholipids may be of importance with respect to the advantageous immunological activity of the fractions B, C and E.

Thus, the term "substantially similar" is intended to mean that the protein content of the fractions B, C and E of the *B. burgdorferi* strain in question is of the same composition as the protein content shown in Fig. 2 even though the molecular weight of the individual proteins may vary, such as it will be illustrated below, or even that one or a few proteins may be missing or be present in excess when compared to the protein distribution pattern of Fig. 2.

In a further aspect, the present invention relates to immunologically active fractions of a *B. burgdorferi* spirochaete strain substantially identical to the immunologically active fractions B, C and E obtained when subjecting the same strain of *B. burgdorferi* spirochaetes to the procedure described in Example 1 as determined by methods of determining substantial identity. Examples of such methods of determining substantial identity are comparison of the protein distribution pattern as obtained by SDS-PAGE analysis and immunological methods, e.g. such as parallel ELISA in which the reactivity of sera with antigens is measured.

The term "substantially identical" is intended to indicate that the fractions have substantially the same protein, lipid, glycolipid and carbohydrate composition, and/or substantially the same immunological properties even though they may have been prepared by another method than that described in Example 1.

In a further aspect, the present invention relates to an immunologically active fraction of *B. burgdorferi*, preferably fraction B of *B. burgdorferi*, having substantially the same reactivity with sera from patients with Lyme disease as that of whole cells of *B. burgdorferi*, but with substantially less reactivity with sera from syphilitic patients.

Because members of the *Borrelia* genus show common antigens with one another and with the treponemes (12)(13) the problem of immunologic cross-reactivity arises when using whole cell preparations in serologic tests. As shown in Table 2 of Example 1, comparable analyses for class-specific IgG antibody have revealed that fraction B shows comparable sensitivity and greater specificity than the whole cell preparation. Furthermore, cross-reactivity with treponemal antibodies is minimal.

Furthermore, in Example 1 it is shown that only 3 of 16 samples from syphilis patients were positive. In Example 5 it is shown that only 1 of 13 mononucleosis patients and 2 out of 70 Anti nuclear antibody (ANA) sera exceeded the cutoff value, i.e. were positive. These results show that use of this fraction, i.e. fraction B, in efforts to detect IgG antibody reduces the number of false positive reactions associated with immune responses to other treponemes. Normally when using whole cells of *B. burgdorferi* for diagnostic purposes, both a serological test for Lyme disease and a diagnostic test for syphilis are required in order to be able to determine the false positive signals and arrive at the desired, correct diagnosis. This complex and time consuming diagnosis method is especially necessary when employing flagellin-enriched whole cell diagnostic agents or diagnostic agents mainly comprising flagellin as the antigenic component. By use of fraction B of the present invention for diagnosis of Lyme disease, only one test is required, namely the serological test. Thus, fraction B of the present invention constitutes a very important and novel tool in the fast and accurate diagnosis of Lyme disease.

Fraction B reacts with a substantial percentage of the sera from patients with Lyme disease, e.g. at least about 85% of the sera from patients with Lyme disease. More preferably, fraction B reacts with at least 87% of the sera from patients with Lyme disease, e.g. with at least 90% of sera from patients with Lyme disease. In an especially preferred aspect, fraction B reacts with at least 95% of the sera from patients with Lyme disease. At the same time, fraction B reacts with an insignificant percentage of the sera of syphilitic patients, e.g. with no more than about 20% of the sera from syphilitic patients.

ents, and preferably with no more than 18% of the sera from syphilitic patients.

Fraction B is a fraction which is still soluble in the mild non-denaturing detergent such as for instance OGP after it has been
5 incubated at 56°C for 30 minutes, but which is substantially insoluble in water.

In another aspect, the present invention relates to an immunologically active fraction C of *B. burgdorferi* spirochaetes as defined above which is still soluble in the mild non-denaturing detergent such as
10 OGP after it has been incubated at 56°C for 30 minutes, and which is substantially soluble in water.

In a further aspect, the present invention relates to an immunologically active fraction E of *B. burgdorferi* spirochaetes as defined above which is substantially not precipitated by a mild non-denaturing detergent such as OGP, but which is precipitated by incubation
15 at 56°C for 30 minutes.

The immunologically active fractions B, C and E described above are substantially free from cell wall and flagellar components of *B. burgdorferi*. In the present context, the term "substantially free" is
20 intended to mean that no substantial reactivity with antibodies against such components is obtained.

The substantial lack of cell wall and flagellar components is, as explained above, believed to be one of the reasons for the very
25 advantageous diagnostic properties of the fractions of the invention.

When the fractions B, C and E have been prepared as outlined above, the immunologically active fractions are substantially free from sodium dodecyl sulfate (SDS). SDS is a strong detergent that probably denatures important epitopes and furthermore interferes with
30 the binding of antigen to microdilution plates (16). In addition, SDS is difficult to remove from e.g. cell fractions containing it. The milder detergents used according to the present invention have not been shown to have these adverse effect.

In another aspect, the present invention relates to immunologically active fractions B, C and E of *B. burgdorferi* spirochaetes of New York strain B31 (ATCC 35210), each fraction being characterized by the following protein bands (expressed as molecular weight in kilodaltons (kd)) in a sodium dodecyl sulfate polyacrylamide gel (containing 10% by weight of sodium dodecyl sulfate polyacrylamide) after electrophoresis at 95-280 V for 5 hours 20 minutes and staining with Coomassie brilliant blue R-250 substantially as disclosed herein:

Fraction B: 20, 21, 29, 31, 34, 39, 59, 66, 68, 85 kd

10 Fraction C: 40, 70 kd

Fraction E: 18, 20, 25, 31, 34, 41, 48, 55, 66, 68, 85 kd

As shown in Fig. 2, the profiles of Coomassie blue-stained proteins and of whole cell and fractionated lysates B, C and E of *B. burgdorferi* differ. When compared with the molecular weight standards, the stained gel reveals the surface proteins of 31 and 34 kd (OspA and OspB) in fractions B, E and in the whole cell lysate of *B. burgdorferi* strain 2591. The presence of OspA in these preparations has been verified by immunoblotting with monoclonal antibody H5332. Likewise, the presence of OspB in the preparations has been verified by immunoblotting with monoclonal antibodies H6831 and H5TS. In fraction C OspA and OspB were absent. The 41 kd protein of flagellin was absent in all three fractions B, C and E. Thus, the 41 kd protein of fraction E stated above did not react with the anti-flagellin monoclonal antibody H9724 in an ELISA and does not react with fractions B and E and does therefore not seem to be flagellin or a related protein. Fraction B also contains other major proteins with apparent molecular weights of 20, 21, 29, 39, 59, 66, 68 and 85 kd. The 39 kd protein did not react with monoclonal antibody H9724, showing that this is not the same as the flagellin antigen. Fraction C contains two proteins with molecular weights of about 40 kd and about 70 kd, respectively. Four proteins in fraction B may prove to be of particular interest, namely the 21, 55, 66 and 85 kd proteins. Antibodies against the 65 and 85 kd proteins have been found in sera from patients with Lyme disease, and these proteins may therefore be important in the *B. burgdorferi* infection, and be potential candidates for

vaccine and diagnostic agent constituents in immunization and diagnosis of Lyme disease. The 66 kd protein is believed to be cleaved to a smaller size when whole cells of *B. burgdorferi* are incubated with proteases such as trypsin and proteinase K.

5 In a further aspect, the present invention relates to immunologically active fractions B, C and E of *B. burgdorferi* spirochaetes of strain ACA-1 as described in Åsbrink et al., 1985 (18), each fraction being characterized by the following protein bands (expressed as molecular weight in kilodaltons (kd)) in a sodium dodecyl sulfate polyacryl-
10 amide gel (containing 15% by weight of sodium dodecyl sulfate polyacrylamide) after electrophoresis at 74 V for 15 hours 15 minutes and staining with Coomassie brilliant blue R-250 substantially as disclosed herein:

15 Fraction B: 13, 15, 19, 23, 24, 25, 28, 30, 32, 36, 38, 41, 47, 50, 59, 68 kd
Fraction C: 14, 32, 36, 52, 68 kd
Fraction E: 11, 14, 25, 30, 32, 36, 47, 50, 54 kd

In the ACA-1 strain, the molecular weight of OspA is 32 kd, as confirmed by analysis against the monoclonal antibody H5332. The abundant protein of molecular weight 36 kd is denoted OspB of strain
20 ACA-1. This is probably equivalent to the OspB of strain B-31 although no immunological cross-reaction could be seen with antibodies H5TS and H6831. The 41 kd protein in fraction B was different from the 41 kd flagellin as verified by analysis against monoclonal anti-
25 body H9724.

As explained above, OspA protein has been isolated from *B. burgdorferi* spirochaetes and immunologically defined as the most abundant protein in whole cell lysates and one that is bound by monoclonal antibody H5332 (12). OspA has been found to be more conserved than
30 OspB. The gene encoding OspA from *B. burgdorferi* strain B31 (ATCC 35210) has been cloned and the present inventors have now succeeded in elucidating the nucleotide sequence of said gene. Accordingly, one aspect of the present invention relates to a DNA fragment comprising the gene encoding OspA as well as the 5'-flanking region of the gene.

The DNA sequence is shown in Fig. 5. The amino acid sequence of OspA has been deduced from the DNA sequence shown in Fig. 5 and is also shown in Fig. 5. The knowledge of the amino acid sequence opens up for a variety of possibilities which have not, prior to the present invention, been possible. These will be explained in detail below.

In the present context, the term "polypeptide" is used in its conventional meaning, i.e. as a sequence of amino acids. The amino acids of the sequence may optionally have been modified, e.g. by chemical, enzymatic or another type of treatment, which does not amend or destroy the immunological activity of the polypeptide to any substantial extent. The polypeptide may be an entire protein, or a subsequence thereof. Especially interesting polypeptides are amino acid sequences comprising epitopes, i.e. antigenic determinants substantially responsible for the antigenic properties of the polypeptide and being capable of evoking an immune response. The minimum amino acid sequence is one which at least comprises a relevant epitope of the polypeptide.

The polypeptides may be in a substantially pure form. In the present context, the term "substantially pure" is understood to mean that the polypeptide in question is substantially free from other components, e.g. other immunologically active components such as *B. burgdorferi* cell wall and flagellar components. Preferably, the polypeptides are preferably free from *B. burgdorferi* spirochaete related components as such. Substantially pure polypeptides having the properties described herein may be prepared by use of recombinant DNA techniques or solid or liquid phase peptide synthesis as will be described in further detail in the following.

In the present context, the term "cell wall" refers to cell components containing the macromolecule, mucopeptide or peptidoglycan which is unique to the cell wall of prokaryotes. Mucopeptide is formed as a continuous net around the cell membrane, conferring both shape and strength to resist osmotic bursting.

The OspA protein of *B. burgdorferi* is further described in Example 2.

mainly on the basis of its amino acid sequence as deduced from the DNA sequence of the cloned ospA gene.

OspA and OspB are outer membrane proteins which are encoded by DNA sequences found within the same operon. The genes encoding OspA and
5 OspB are located on linear plasmids. Both proteins are believed to be almost completely cleaved from the cell with proteases (26, 25), though it is possible that OspA and OspB are anchored to the outer membrane of the cells without signal sequence and thus without being cleaved at all. The sequence of the gene encoding OspB has been
10 revealed (38) and the amino acid sequence of OspB has been deduced on the basis of the nucleotide sequence. By the present invention, it is now possible to compare the amino acid sequences of OspA and OspB. An overall sequence identity of 53% has been found. Further, it has been found that substantially the following amino acid sequence is
15 common to OspA and OspB:

L-x-x-x-x-L-x-L-x-L-A-L-I-x-C, wherein

L is a lysine residue
A is a alanine residue
I is a isoleucine residue
20 C is a cysteine residue
x is a non-charged amino acid residue.

The above amino acid sequence starts at residue 5 in OspA and in residue 4 of OspB. The above sequence is expected to be common to other outer surface proteins of *B. burgdorferi*. Also the predicted
25 consensus sequences of the signal sequences of OspA as well as OspB are similar. Thus, the following sequence

L-Z-Z-C, wherein

L and C have the above defined meaning and Z is predominantly a small, neutral amino acid, in OspA, isoleucine and alanine, and in
30 OspB, isoleucine and glycine, has been found around the peptidase cleavage site of the signal peptide. This is contemplated to apply for other outer surface proteins of *B. burgdorferi* as well.

The hydropathic index and the hydrophilicity profile of the predicted OspA sequence as determined by computer analysis according to Kyle et al., 1982 (20) are shown in Fig. 6 and Fig. 7, respectively. The estimated 16 amino acid signal sequence of OspA is highly hydrophobic and the remaining part of OspA contains several hydrophobic regions.

OspA has the following N-terminal sequence

M-K-K wherein

M is a methionine residue, and

K is a lysine residue, and a possible candidate for the anchorage of OspA to the outer membrane.

The secondary structure of the estimated amino acid sequence has also been elucidated by use of computer analysis according to Kyle et al., 1982 (20). The results are illustrated in Figs. 9-13.

As will be appreciated from the above explanation, the most interesting parts of OspA in the present context are the parts being responsible for the immunological activity of OspA, i.e. the antigenic determinants or epitopes. The deduced amino acid sequence of OspA has been analyzed so as to reveal possible highly antigenic sequences. The following polypeptides are, based on this analysis, contemplated to be epitopes of the OspA protein:

Lys-Glu-Lys-Asn-Lys-Asp

Ser-Lys-Lys-Thr-Lys-Asp

Lys-Ala-Asp-Lys-Ser-Lys

and thus contemplated to be capable of evoking an immune response in animals.

The polypeptide described above may be produced by recombinant DNA techniques, such as will be further explained below, or by conventional liquid or solid phase peptide synthesis. In solid phase synthesis, e.g. as described by R.B. Merrifield, 1963 (31), the amino acid

sequence of any of the above described polypeptides is constructed by coupling an initial amino acid to a solid support and then sequentially adding the other amino acids in the sequence by peptide bonding until the desired length has been obtained. The solid support may
5 also serve as the carrier for the polypeptide described above in the vaccine preparation described below. The preparation of synthetic peptides for use as vaccines may be carried out essentially as described in Shinnick, 1983 (32).

As explained above, one or more of the fractions B, C and E of *B. burgdorferi* spirochaetes may be obtained by a method comprising the
10 following steps:

- a) lysing *B. burgdorferi* spirochaete cells with a mild non-denaturing detergent so as to release outer membrane and cytoplasmic components from the cells, and subsequently subjecting
15 the lysed cells to centrifugation resulting in a first pellet comprising cell wall and flagellar components and a first supernatant comprising outer membrane and cytoplasmic components,
- b) incubating the first supernatant from step a) under conditions sufficient to precipitate at least part of the proteins of the
20 first supernatant followed by centrifugation so as to obtain a second pellet comprising fraction E and a second supernatant,
- c) subjecting the second supernatant from step b) to filtration, and 1) dialyzing the supernatant against an aqueous medium with a low ionic strength or 2) subjecting the supernatant to ultra-
25 filtration so as to substantially remove the mild non-denaturing detergent and complex *B. burgdorferi* derived cell components in the dialysis bag or in the filtrate resulting from the ultrafiltration,
- d) centrifugating the contents of the dialysis bag or the filtrate
30 resulting from the ultrafiltration so as to obtain a third pellet comprising fraction B and a third supernatant comprising fraction C.

The *B. burgdorferi* spirochaete cells have preferably been washed prior to being subjected to the method of the invention so as to remove impurities and other irrelevant components.

Although, as stated above, the method of the invention may seem to resemble other known methods of fractionating *B. burgdorferi* cells, each of the steps of the method has been specifically constructed in order to be able to obtain each of the fractions B, D and E of the invention.

Preferably, the mild non-denaturing detergent used in step a) is a non-denaturing and water-dialysable detergent. Non-ionic, zwitterionic and anionic detergents have been found to be useful, vide Example 3. Specific examples of useful detergents are listed in Example 3. The effect of the detergent is illustrated in the following with reference to the mild non-denaturing, non-ionic detergents octyl- β -D-glucopyranoside (OGP) which have proved to be very useful. However, the same effect is obtained when using other detergents of the above mentioned type, e.g. the specific useful detergents listed in Example 3, and the method of the invention should not be understood to be limited to the use of this specific detergent.

OGP serves to release the outer membrane from the cell, and thus to substantially separate the outer membrane from the inner protoplasmic cylinder and flagella. The release of the outer membrane causes lysis of the cells. It is believed that the outer membrane components are released into the lysed cell suspension during the OGP treatment whereas important immunogenic cell wall and flagellar components are substantially retained in the insoluble cell residue. This is believed to be one of the important effects of OGP. It is very advantageous to substantially avoid release of immunogenic cell wall and flagellar components, especially the immunogenic flagellin, into the medium as these components are supposed to be responsible for the cross-reactivity with sera from patients with other infections than these.

As mentioned above, other cellular components than proteins may be released or modified by the treatment with OGP. Thus, carbohydrates and lipids such as glycolipids and phospholipids as well as other

cellular components may be found in, and isolated together with outer membrane components. These non-proteinaceous components may be responsible for or add to the immunological activity of the fractions B, C and E recovered in the later steps of the method outlined above.

- 5 The conditions under which the treatment with the mild non-denaturating detergent according to step a) of the method is performed should be adapted so as to ensure that the above explained effects of the treatment are obtained. Thus, the temperature at which the treatment is carried out should be a temperature at which the mild non-denaturating detergent is capable of exerting its membrane releasing activity and other activities essential for the fractionation and at which the immunological properties of the components of the fractions are substantially maintained. For instance, the temperature should be chosen so as to ensure that the protein components of the fractions B, C and E have not lost their immunological activity to an extent which will make the fractions B, C or E useless as immunologically active fractions.

- Preferably, the lysis with the mild non-denaturating detergent is performed at a temperature in the range of about 20-60°C. At temperatures above about 60°C, the outer membrane releasing capacity of the mild non-denaturating detergent, e.g. the OGP, is presumed to be reduced, and also the proteins and other cell components may be denatured or modified so that a substantial part of their immunological activity is lost. At temperatures lower than about 20°C, the outer membrane releasing activity of the mild non-denaturating detergent, e.g. OGP, is believed to be too low to obtain a sufficient release of the outer membrane and the immunologically active components of the fractions. Temperatures in the range of about 25-50°C, such as about 30-40°C are believed to be especially suitable for the treatment of the *B. burgdorferi* spirochaetes with the mild non-denaturating detergent, and a temperature of about 37°C has been found to result in the desired fractions B, C and E.

- Also the concentration or type of detergent in which the detergent is used will, of course, be of importance in order to obtain the desired result. Normally, the mild non-denaturating detergent is used in a

concentration in the range of 0.1-2%. The use of the mild non-denaturing detergent in a concentration above about 2.0% will normally not serve to enhance the outer membrane releasing capability of the OGP and will therefore be superfluous. Concentrations below about
5 0.1% will in most cases not be sufficient to obtain the desired release of the outer membrane and components related thereto. Preferably, the detergent is used in a concentration of 0.2-1%.

As stated above, the cells treated with the mild non-denaturing detergent are subjected to centrifugation so as to obtain a pellet
10 and a supernatant. Centrifugation has been found to be the easiest way of separating the components of the lysed spirochaete cells, but other separating methods may also be useful. Thus, such other methods should also be understood to be comprised by the present invention.

The spirochaetes may be preconditioned to the lysis by sonication in
15 accordance with conventional techniques and optionally solely be subjected to sonication.

The first pellet obtained by the centrifugation or an equivalent treatment comprises mostly cell debris such as cell wall and flagellar components as well as other subcellular components which have
20 been released by treating the cells with the mild non-denaturing detergent. Such other components are for instance insoluble or heavily insoluble substances or particles such as ribosomes. The supernatant resulting from the centrifugation or an equivalent treatment comprises mainly outer membrane components such as proteins related
25 to the outer membrane, e.g. the proteins stated above in connection with fraction B, C and E of the investigated *B. burgdorferi* strains and corresponding proteins from other *B. burgdorferi* strains. However, also carbohydrates, lipids such as glycolipids and phospholipids, which may have immunological activity, are present in the
30 supernatant resulting from the separation treatment.

Subsequent to the separation, the first supernatant is incubated under conditions which are sufficient to precipitate at least part of the proteins of the first supernatant. This is the incubation of step b) above. One condition which has been found sufficient to obtain the

desired precipitation is heating of the supernatant. Thus, the incubation of the supernatant is preferably carried out at an elevated temperature, at which precipitation is allowed to occur. Typically, such a temperature will be in the range of about 45-65°C. It is well known that proteins when subjected to heating coagulate and the precipitate obtained in step b) is believed to comprise such coagulated proteins. Also other components present in the first supernatant may, however, precipitate when being subjected to heating.

At temperatures above about 65°C, the denaturation of proteins is believed to be extensive and thus, it is believed that immunologically active components of the supernatant are destroyed. At temperatures below 45°C, the precipitation is believed to be insufficient with regard to the desired precipitation. Normally, it is desired that the incubation is carried out at a temperature of about 50-60°C, such as about 56°C, which is the temperature normally known to cause conglomeration of a wide variety of proteins, and which has actually been shown to provide an optimum precipitation of proteins, vide Example 3b.

The precipitate resulting from the incubation according to step b) is subsequently separated from the supernatant. Preferably, the separation is accomplished by centrifugation, but other separation methods may also be employed as long as the necessary separation of the precipitate and the supernatant occurs. The pellet obtained by the separation procedure, e.g. the centrifugation, comprises at least part of the components precipitated during the incubation and comprises the above defined fraction E of the *B. burgdorferi* spirochaete cells. The pellet comprising fraction E may optionally be subjected to further purification by incubation with a detergent, such as sodium lauryl sarcosinate (Sarkosyl), centrifugation of the incubated mixture or an equivalent treatment to separate the incubation mixture resulting in a fourth pellet and a fourth supernatant, and subsequently dialyzing the supernatant against a detergent-removing agent such as an aqueous alcohol, e.g. methanol, or subjecting the supernatant to ultrafiltration so as to substantially remove the detergent. The alcohol is preferably an aqueous alcohol in a concentration of 10-25% (v/v). Then, the contents of the dialysis bag or the filtrate resulting

from the ultrafiltration may be centrifugated, resulting in a third pellet comprising the purified fraction E. In addition to removing the detergent, the dialysis is believed to lead to the formation of complexes of components present in fraction E. Any conventionally
5 used dialysis bags or other dialysis equipment as well as ultrafiltration equipment may be used for the removal of the detergent and the optional complex formation of certain of the components contained in the dialysis bag or filtrate. Preferably, when the detergent-removing agent is an alcohol, dialysis is employed for the removal of
10 the alcohol. An example of a suitable dialysis bag is the one employed in Example 1. For the ultrafiltration, a membrane which has been found useful is one having pores, i.e. cut-off value, of substantially the same size as the pores of the dialysis bag, e.g. a pore size or cut-off value in the range of about 2,000-15,000, such as about
15 3,000-8,000 and preferably of about 5,000-6,000.

The second supernatant resulting from step b) of the above method is subjected to filtration so as to remove insoluble particles and avoid contamination before ultrafiltration. If the preceding centrifugation has been very effective, this filtration step may be omitted, but in
20 most cases, the mixture subjected to the preceding centrifugation contains particles or other components which may not be spun down to any suitable extent during the centrifugation treatment and therefore in these cases, the filtration is required. The resulting filtrate is suitably dialyzed against an aqueous medium with a low ionic
25 strength or subjected to ultrafiltration. The low ionic strength, e.g. an ionic strength below 0.3M is believed to be required so as to substantially avoid interference of the ions of the aqueous medium with the detergent which would lead to an incomplete removal of the detergent. Preferably, the ionic strength is below 0.2M such as below
30 0.1M. The dialysis serves the purpose of substantially removing the mild non-denaturing detergent, and it is also believed that some of the *B. burgdorferi* derived cell components are precipitated when the detergent is removed.

The aqueous medium against which the dialysis is carried out is preferably
35 water. The water may be distilled, sterilized, deionized or may be simple tap water, e.g. containing various ions such as cal-

cium, magnesium, sodium, carbonate, chloride and sulfate ions and the like.

The filtration may be carried out in different ways and serves the purpose of separating some of the large components, e.g. insoluble particles, from the supernatant. Conveniently, the filtration is a microfiltration through a membrane, e.g. through a membrane having a pore diameter of at the most about 2.0 μm . A more efficient filtration is obtained by using membranes having a pore diameter of at the most 0.60 μm . More preferably, the pore diameter of the membrane is at the most 0.45 μm . For some purposes, it may be advantageous to use membranes having a pore diameter of at the most 0.30 μm such as at the most 0.20 μm .

The centrifugation treatments of the above explained methods should be performed under conditions ensuring the desired, sufficient separation of the components of the suspension. The time during which the centrifugation is carried out as well as the speed of the rotor should be adapted so as to obtain the desired separation, e.g. what is sufficient to obtain a pellet. For this purpose, one or more centrifugation treatments may be employed. In most cases, a centrifugation at above about 30,000 x g such as above about 35,000 x g, e.g. about 45,000 x g has been found to be useful, when performed for at least about 10 minutes, such as at least about 20 minutes. However, centrifugation at up to about 150,000 x g may be used. Generally, the longer the centrifugation time and the higher the speed, the more efficient separation of the suspension of components to be separated is obtained.

In another embodiment, the present invention relates to a DNA fragment encoding the 31 kd Ospa protein of *B. burgdorferi* of the New York strain B31 (ATCC 35210), which DNA fragment further contains the 5'-flanking region of the *ospA* gene, or any modification of said sequence encoding a polypeptide which is functionally equivalent to Ospa.

The term "functional equivalent" is intended to include all immunogenically active substances with the ability of evoking an immune

response in animals, including humans, to which the equivalent polypeptide has been administered, e.g. as a constituent of a vaccine or a diagnostic agent, which immune response is similar to the immune response evoked by the OspA protein. Thus, equivalent polypeptides
5 are polypeptides capable of conferring immunity to Lyme diseases.

The DNA fragment encoding OspA or a part thereof may be subjected to mutagenization, e.g. by treatment with ultraviolet radiation, ionizing radiation or a chemical mutagen such as mitomycin C, 5-bromouracil, methylmethane sulphonate, nitrogen mustard or a nitrofurantoin so as
10 to alter some of the properties of the gene product expressed from the mutagenized sequence substantially without amending the immunologic activity of the gene product. Especially, site-directed mutagenesis or directed mutagenesis is useful.

Preferably, the DNA fragment according to the present invention
15 substantially comprises the DNA sequence shown in Fig. 5 or a part thereof. As explained above, the DNA sequence shown in Fig. 5 is believed to be the sequence encoding the 31 kd OspA protein of *B. burgdorferi* of the New York strain B31 (ATCC 35210). The DNA fragment shown in Fig. 5 further contains the 5 prime-end flanking region of
20 the *ospA* gene.

The DNA sequence shown in Fig. 5 is discussed in detail in Example 2 herein.

The DNA fragment of the invention may be one which has been modified by substitution, addition, insertion or deletion of one or more nucleotides in the sequence for the purpose of establishing a sequence
25 which, when expressed in a suitable host organism, results in the production of a protein or polypeptide with a substantial similarity to the OspA protein or a polypeptide part thereof, which has the desired immunological activity.

Especially interesting DNA fragments are fragments which encode immunologically active parts of OspA, i.e. the antigenic determinants or epitopes of OspA. Thus, the DNA fragments encoding the polypeptides
30

listed above being contemplated to possess highly immunogenic properties, are especially interesting.

The DNA fragment illustrated in Fig. 5 or a part of said fragment may be derived by screening *B. burgdorferi* for nucleotide sequences hybridizing to a DNA probe prepared on the basis of the full or partial nucleotide sequence shown in Fig. 5. Further, the nucleotide sequence may be a synthetic sequence, i.e. a sequence which is prepared according to standard procedures, e.g. as described in Matthes et al., 1984 (29).

- 10 The DNA fragment of the invention may be used for the production of OspA or a part thereof, especially an immunologically active part thereof. For this purpose, conventional recombinant DNA techniques may be employed. Thus, techniques comprising inserting the DNA fragment of the invention or one or more parts thereof into a suitable expression vector, transforming a host organism with the vector, 15 cultivating the organism under conditions allowing expression of the inserted sequence and harvesting the resulting gene product, OspA or a part thereof, will be useful. Any of these procedures may be carried out by standard methods such as those disclosed in Maniatis et al., 1982 (30). 20

Suitable expression vectors for the production of OspA or a part thereof are vectors which is capable of replicating in a host organism when transformed therein. The vector may either be one which is capable of autonomous replication, such as a plasmid, or one which is replicated with the host chromosome, such as a bacteriophage. Examples of suitable vectors which have been widely employed are pBR322 and related vectors as well as pUC vectors and the like. Examples of suitable bacteriophages include M13 and λ . 25

The organism harbouring the vector carrying the DNA fragment shown in Fig. 5 or part thereof may be any organism which is capable of expressing said DNA fragment. The organism is preferably a microorganism such as a bacterium. Gram-positive as well as gram-negative bacteria may be employed. Especially a gram-negative bacterium such as *E. coli* is useful, but also gram-positive bacteria such as *B.* 30

subtilis and other types of microorganisms such as yeasts or fungi or other organisms conventionally used to produce recombinant DNA products may be used.

Another type of organism which may be used to express OspA or a part thereof is a higher eukaryotic organism or cell, including a plant and mammal cell. However, also higher organisms such as animals, e.g. sheep, cattle, goats, pigs, horses and domestic animals, including cats and dogs, are contemplated to be useful as host organisms for the production of OspA or a part thereof. When a higher organism, e.g. an animal, is employed for the production of OspA or a part thereof, conventional transgenic techniques may be employed. These techniques comprise inserting the DNA fragment shown in Fig. 5 or one or more parts thereof into the genome of the animal in such a position that OspA or part thereof is expressed together with a polypeptide which is inherently expressed by the animal, preferably a polypeptide which is easily recovered from the animal, e.g. a polypeptide which is secreted by the animal, such as a milk protein or the like. Alternatively, the DNA fragment of the invention could be inserted into the genome of the animal in a position allowing the gene product of the expressed DNA sequence to be retained in the animal body so that a substantial steady immunization of the animal takes place.

When a microorganism is used for expressing the DNA fragment of the invention, the cultivation conditions will typically depend on the type of microorganism employed, and the skilled art worker will know which cultivation method to choose and how to optimize this method.

The production of OspA or a part thereof by recombinant techniques has a number of advantages: it is possible to produce OspA or part thereof by culturing non-pathogenic organisms or other organisms which do not affect the immunological properties of OspA or part thereof, it is possible to produce OspA in higher quantities than those obtained when recovering OspA from any of the above described fractions B, C and E, and it is possible to produce parts of OspA which may not be isolated from *B. burgdorferi* strains. The higher quantities of OspA or parts thereof may for instance be obtained by

using high copy number vectors for cloning the DNA fragment of the invention or by using a strong promoter to induce a higher level of expression than the expression level obtained with the promoters P1 and P2 present on the DNA fragment of the invention. By use of recombinant DNA techniques for producing OspA or parts thereof, unlimited amounts of a substantially pure protein or polypeptide which is not "contaminated" with other components which are normally present in *B. burgdorferi* isolates may be obtained. Thus, it is possible to obtain a substantially pure OspA protein, i.e. OspA which is not admixed with other *B. burgdorferi* proteins which have an adverse effect when present in a vaccine or a diagnostic agent in which the OspA is an intended constituent. A substantially pure OspA protein or a polypeptide part thereof has the additional advantage that the exact concentration thereof in a given vaccine preparation is known so that an exact dosage may be administered to the individual to be immunized.

An important aspect of the present invention concerns a vaccine for the immunization of a mammal, including a human being, against Lyme disease, which vaccine comprises an immunologically effective amount of any one of the above defined fractions B, C and E or combinations thereof together with an immunologically acceptable carrier or vehicle.

The term "immunization" is understood to comprise the process of evoking a specific immunologic response with the expectation that this will result in humoral, and/or secretory, and/or cell-mediated immunity to infection with *Borrelia* species, i.e. immunity is to be understood to comprise the ability of the individual to resist or overcome infection or to overcome infection more easily when compared to individuals not being immunized or to tolerate the infection without being clinically affected. Thus, the immunization according to the present invention is a process of increasing resistance to infection with *Borrelia* species.

In another aspect, the present invention relates to a vaccine comprising an immunogenically effective amount of a polypeptide as described above, i.e. the entire OspA protein or an immunogenic part thereof, e.g. an epitope or an antigenic determinant of the OspA protein.

Also, a vaccine comprising an immunogenically effective amount of one or more of the proteins present in any of the fractions B, C and E described above may be of interest. Thus, a vaccine comprising the 20, 21, 29, 31, 34, 39, 59, 66, 68, 85 kd proteins of fraction B, the 40, 70 kd proteins of fraction C, and the 18, 20, 25, 31, 34, 41, 48, 55, 66, 68, 85 kd proteins of fraction E may be of interest. It is contemplated that a vaccine comprising the polypeptides with molecular weights of 55 and 85 kd of fraction B as well as of 31, 34 and 66 kd may be of particular interest as these proteins have been found to give rise to a suitable immune response. Also, antibodies against the polypeptides with a molecular weight of 55 and 85 kd have been found in sera from patients infected with *B. burgdorferi* strains, indicating that these proteins exert an immunological activity. The molecular weights of the proteins given above are the molecular weights of the proteins isolated from the *B. burgdorferi* strain B31 (ATCC 35210), and proteins isolated from other *B. burgdorferi* strains corresponding to these proteins, although not having the same molecular weights, are of course also interesting as vaccine components. A vaccine comprising one or more of the polypeptides described above, i.e. OspA or parts thereof, in combination with one or more of the proteins described above may be especially useful. Also, vaccines constituting one or more of the polypeptides described above and immunologically active components from other organisms may be desirable.

The immunologically acceptable carrier or vehicle being part of the vaccine may be any carrier or vehicle usually employed in the preparation of vaccines. Thus, the vehicle may be a diluent, a suspending agent or other similar agents. The vaccine may be prepared by mixing an immunogenically effective amount of any of the fractions B, C and E, the polypeptides defined above, one or more proteins of the fractions or a combination of any of these with the vehicle in an amount resulting in the desired concentration of the immunogenically effective component of the vaccine. The amount of immunogenically effective component in the vaccine will of course depend on the animal to be immunized, e.g. the age and the weight of the animal, as well as the immunogenicity of the immunogenic component present in the vaccine. For most purposes, an amount of the immunogenic compo-

5 nent of the vaccine will be in the range of 5-500 μ g. The methods of preparation of vaccines according to the present invention are designed to ensure that the identity and immunological effectiveness of the specific molecules are maintained and that no unwanted microbial contaminants are introduced. The final products are distributed under aseptic conditions into preferably sterile containers which are then sealed to exclude extraneous microorganisms.

10 As stated above, the OspA protein or part thereof, the amino acid sequence of which is shown in Fig. 5, may be prepared by recombinant DNA techniques or by solid or liquid phase peptide synthesis. Polypeptides prepared in this manner are especially desirable as vaccine components as these polypeptides are essentially free from other contaminating components which will influence the immunogenic properties of the polypeptides. Thus, polypeptides prepared by recombinant
15 DNA techniques or by solid or liquid phase peptide synthesis may be obtained in a substantially pure form which is very desirable for vaccine purposes.

20 When proteins or other immunogenically active components present in any of fractions B, C and E are employed as vaccine constituents, these may advantageously be recovered from the fractions by any conventional method, e.g. a method in which antibodies, preferably monoclonal antibodies, reactive with the proteins or other immunologically active components of fractions B, C and E are immobilized to a matrix, the matrix is contacted with the fraction B, C or E in
25 question, washed, and finally the antigen-antibody complex fixed to the matrix is treated so as to release the *B. burgdorferi* related proteins or other immunologically active components in a purified form. A preferred way is to isolate the *B. burgdorferi* related proteins by means of column affinity chromatography involving antibodies
30 fixed to the column matrix.

Also, other procedures involving various forms of affinity chromatography, gel filtration, ion exchange or high performance liquid chromatography (HPLC), may be employed.

Alternatively, preparative electrophoresis procedures may be employed. Thus, fractions B, C or E are subjected to a gel electrophoresis, such as a sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) or an agarose gel electrophoresis. Conveniently, two
5 parallel gels are run. One of the gels is stained and analyzed by visual inspection, and the location of the desired protein bands on the gel is found. The corresponding protein bands on the other unstained gel are then cut out of the gel. The protein-containing gel parts are treated so as to release the *B. burgdorferi* proteins from
10 the gel, such as procedures involving slicing up the gel and subsequent elution of *B. burgdorferi* related proteins.

The vaccine may further comprise an adjuvant in order to increase the immunogenicity of the vaccine preparation. The adjuvant may be selected from Freund's complete or incomplete adjuvant, aluminum
15 hydroxide, a saponin, a muramyl dipeptide, an iscome and an oil, such as a vegetable oil, e.g. peanut oil, or a mineral oil, e.g. silicone oil.

In some cases it may be advantageous to couple the immunogenic component(s) to a carrier, in particular a macromolecular carrier. The
20 carrier is usually a polymer to which the immunogenic component(s) is/are bound by hydrophobic non-covalent interaction, such as a plastic, e.g. polystyrene, or a polymer to which the immunogenic component(s) is/are covalently bound, such as a polysaccharide, or a polypeptide, e.g. bovine serum albumin, ovalbumin or keyhole limpet
25 hemocyanin. The carrier should preferably be non-toxic and non-allergenic. The immunogenic component(s) may be multivalently coupled to the macromolecular carrier as this provides an increased immunogenicity of the vaccine preparation. It is also contemplated that the immunogenic component(s) may be presented in multivalent form by
30 polymerizing the immunogenic component(s) with itself.

In this regard, it may prove advantageous to couple the immunogenic component to the carrier together with one or more immunologically active molecules obtained from organisms other than *B. burgdorferi* so as to obtain a vaccine comprising a variety of different immunogenic
35 determinants, being a cocktail vaccine, which may be employed for the

immunization against diseases caused by other organisms, e.g. organisms responsible for relapsing fever or syphilis.

In another embodiment, a mixture of two or more single vaccines may be employed.

5 It is known that antibodies raised against *B. burgdorferi* or parts thereof evoking an immune response have a rather short lifetime in sera of animals and humans. Thus, a suitable strategy for immunizing animals and humans against Lyme disease is to periodically administer the vaccine described above to individuals subjected to contact with
10 ticks bearing *B. burgdorferi*. It is contemplated that vaccination once a year such as in the springtime will provide a suitable protection of individuals in risk of *B. burgdorferi* infection. A suitable dose of immunogenic components for such a vaccination is 5-500 μ g. However, also more irregular immunizations may be advantageous, and
15 any immunization route which may be contemplated or shown to produce an appropriate immune response can be employed in accordance with the principle of the present invention. Suitable administration forms of the vaccine of the invention are oral administration forms, e.g. tablets, granules or capsules, subcutaneous, intracutaneous or in-
20 tramuscular administration forms or forms suitable for nasal or rectal administration.

As stated above, recombinant DNA technologies are useful for the preparation of diagnostic reagents and vaccines. Routine methods for vaccine production involve risks of obtaining unwanted side effects,
25 e.g. due to the vaccine containing unwanted (or even unidentified) contaminants. An alternative approach to the production of new vaccines involves the insertion of one or more DNA sequences constituting one or more parts of the DNA sequence shown in Fig. 5 or parts thereof into a virus genome, e.g. into a retrovirus, vaccinia virus
30 or Epstein-Barr virus genome, to produce a polyvalent vaccine. An especially interesting virus for the present purpose is vaccinia. Also, synthetic polypeptides which have been prepared by conventional methods, e.g. by solid or liquid phase peptide synthesis, are suitable for vaccines.

In a further aspect, the present invention relates to a non-pathogenic microorganism which carries and is capable of expressing an inserted nucleotide sequence which is the nucleotide sequence shown in Fig. 5 or part thereof for use as a live vaccine for the immunization of an animal against Lyme disease. For instance, the use of a live vaccine might be advantageous since it is presumed that vaccines based on living organisms show an excellent immunogenicity, and it is also contemplated that the use of a live vaccine will confer a life-long immunity against Lyme disease so that repeated vaccination will not be needed.

In a particularly advantageous embodiment of the live vaccine of the invention, the DNA fragment of the invention is expressed on the outer surface of the host microorganism. This provides a favourable presentation of the immunologically active part(s) of OspA recognized by the immune defense mechanisms of the animal to which the live vaccine is administered, thus provoking an appropriate immune response. One way of providing the expression of OspA or immunologically active part(s) thereof (the epitopes) on the cell surface is to fuse the DNA fragment of the invention to another nucleotide sequence encoding a surface protein or a subsequence thereof (e.g. a signal peptide) which cause the *B. burgdorferi* epitopes to be expressed on the outer surface of the host cell, optionally as a fused polypeptide. Examples of useful surface proteins are adhesins, fimbrial proteins, or other extracellular proteins.

The microorganism used for live vaccines should be a non-pathogenic microorganism, e.g. a non-pathogenic *E. coli*, which may be able to establish itself in the animal body. A microorganism which may prove especially useful as a live vaccine may be the *B. burgdorferi* in itself, which as explained above inherently expresses OspA on the surface of the cell. The use of *B. burgdorferi* for a live vaccine requires, however, that the *B. burgdorferi* has been altered so as to not cause any illness when used as a live vaccine. This alteration or modification may be carried out in any suitable manner, e.g. by mutagenization, chemical, enzymatic or heat treatment, or by another equivalent treatment resulting in an attenuated *B. burgdorferi* cell.

In another aspect of the present invention, passive immunization is employed, i.e. a preparation containing antibodies raised against the immunogenic components of the present invention, i.e. any of fractions B, C and E or the proteins contained therein as well as the OspA protein and immunogenic parts thereof, is administered to the individual to be immunized. In most cases preparations with a high content of purified antibodies are favourable. Useful antibodies for this purpose will be described below.

As is explained above, fractions of *B. burgdorferi* spirochaetes selected from fractions B, C and E defined above or polypeptides encoded by the DNA sequence shown in Fig. 5 or parts thereof are useful in immunization against Lyme disease and in the preparation of a composition for the immunization against Lyme disease, i.e. as vaccine components.

In a further important aspect, the present invention relates to a diagnostic agent for the detection of *B. burgdorferi* antibodies in a sample, which agent comprises one or more fractions of *B. burgdorferi* spirochaetes selected from fractions B, C and E defined above. Further, the present invention relates to a diagnostic agent for the detection of *B. burgdorferi* antibodies in a sample, which agent comprises one or more polypeptides encoded by the DNA fragment shown in Fig. 5 or part thereof, or one or more of the proteins contained in any of the fractions B, C and E defined above or a combination of one or more of the polypeptides encoded by the DNA fragment or parts thereof and the proteins of the fractions.

As explained above, *B. burgdorferi* strains of different geographical origin differ in their protein profiles as judged by Coomassie-staining of PAGE gels (cf. Examples 1 and 5). Thus, the pattern of antibody responses, besides being dependent on the stage of infection, may vary between individuals from different parts of the world. Therefore, it may prove advantageous to use a mixture of two or more fractions isolated from different *B. burgdorferi* strains in a diagnostic agent to be used in various parts of the world. For instance, the use of one fraction of european origin and one of american origin, e.g. a fraction B of each origin, may provide a diagnostic agent

which allows detection of *Borrelia* specific antibodies of these geographical origins. If the diagnostic agent comprises fractions of sufficiently varied geographical origins, it may be possible to detect *Borrelia*-specific antibodies regardless of the origin of the
5 infecting bacteria.

Any of the fractions B, C or E of *B. burgdorferi* or the immunologically active components therein, e.g. the immunologically active proteins, carbohydrates, or lipids, or OspA or immunologically active parts thereof for antibodies raised against these immunologically
10 active fractions or components may be used as diagnostic reagents for the determination of the presence of *B. burgdorferi*. As will be apparent to a person skilled in the art, several techniques may be applied in connection with such diagnostic reagents. Thus, preferred embodiments of the invention are based on immunological reactions
15 between antigens and antibodies, detection of said reaction and correlating the results obtained with results from reference reactions. Preferred assays of the invention are enzyme immunosorbent assays such as enzyme linked immunosorbent assays (ELISA), radio immuno assays (RIA), immuno electrophoresis assays and the like.

20 The ELISA and RIA methods are well established and may be carried out with existing laboratory equipment and may also be subjected to automation. The methods of the invention therefore have wide applicability in clinical laboratories for diagnostic purposes and for monitoring the results of vaccination procedures, and in the pharmaceutical
25 industry as an assay for immunogens to be used in the production of vaccines.

The term "sample" applies to any material to be tested for the presence of *B. burgdorferi* and related components, e.g. immunologically active components present on *B. burgdorferi* as well as antibody
30 raised against these components. Preferably, the sample constitutes part of a living organism such as a human or an animal and may be an anthropod tissue, e.g. an ixodid tick tissue. The sample may be any sample obtained from a human or an animal cavity containing *B. burgdorferi* cells or components thereof. Thus, the sample may be selected
35 from body tissues or body fluids such as blood, serum, urine, cere-

brospinal fluid, joint fluid, and pericardial fluid. Also suspensions and homogenates of cell tissues are included in the definition of sample tissues such as ixodid tick tissues. Examples of sample types are skin parts from the infected organism and samples from the parodontal region of the infected animal.

The identification and/or quantification of *B. burgdorferi* antibodies present in a sample as well as of immunologically active parts of *B. burgdorferi* or *B. burgdorferi* cells may be performed according to the present invention and may be any identification and/or quantification involving these *B. burgdorferi* related components. Thus, both a qualitative and a quantitative determination of *B. burgdorferi* related components may be obtained according to the present invention. The identification and/or quantification may be performed for both a scientific, a clinical and an industrial purpose.

Although in some cases such as when the diagnostic agent is to be employed in an agglutination assay in which solid particles to which the antigen is coupled agglutinate in the presence of a *B. burgdorferi* antibody in the sample subjected to testing, no labelling of the monoclonal antibody is necessary, it is preferred for most purposes to provide the antibody with a label in order to detect bound antibody. In a double antibody ("sandwich") assay, at least one of the antibodies may be provided with a label.

The substance used as label may be selected from any substance which is detectable in itself or which may be reacted with another substance to produce a detectable product. Thus, the label may be selected from radioactive isotopes, enzymes, chromophores, fluorescent or chemiluminescent substances, and complexing agents.

Examples of enzymes useful as labels are β -galactosidase, urease, glucosidases, glucose oxidase, carbonic anhydrase, peroxidases (e.g. horseradish peroxidase), phosphatases (e.g. alkaline or acid phosphatase), glucose-6-phosphate dehydrogenase, murinase and ribonuclease.

Enzymes are not in themselves detectable, but must be combined with a substrate to catalyze a reaction the end product of which is detect-

able. Thus, a substrate may be added to the reaction mixture resulting in a coloured, fluorescent or chemiluminescent product or in a colour change or in a change in the intensity of the colour, fluorescence or chemiluminescence. Examples of substrates which are useful in the present method as substrates for the enzymes mentioned above are H_2O_2 , p-nitrophenylphosphate, lactose, urea, β -D-glucose, CO_2 , RNA, starch, or malate. The substrate may e.g. be combined with a chromophore which is either a donor or acceptor.

It has been found that labels of non-animal, including non-human origin, are especially useful in the detection of *B. burgdorferi* antibodies, as these labels are not naturally present in the animal or human sera to be tested. When using substances naturally present in animal or human serum as labels, e.g. using alkaline phosphatase as a label, these substances of serum origin may contribute to the signal obtained in the determination employing these substances as a label and thus result in a value which is too high for representing the amount of bound antibody from the sample. Thus, labels of plant origin have been found to be very useful, e.g. labels comprising plant peroxidases, such as horseradish peroxidase.

Fluorescent substances which may be used as labels for the detection of the components as used according to the of invention may be 4-methylumbelliferyl-phosphate, 4-methylumbelliferyl-D-galactopyranoside, and 3-(p-hydroxyphenyl) propionic acid. These substances may be detected by means of a fluorescence spectrophotometer. Chemiluminescent substances which may be employed are peroxidase/eosin/EDTA, isoluminol/EDTA/ H_2O_2 and a substrate therefor.

Chromophores may be o-phenylenediamine or similar compounds. These substances may be detected by means of a spectrophotometer. Radioactive isotopes may be any detectable isotope which is acceptable in a laboratory, e.g. ^{125}I , ^{131}I , ^3H , ^{35}P , ^{35}S or ^{14}C . The radioactivity may be measured in a γ -counter or a scintillation counter.

Complexing agents may be Protein A (which forms a complex with immunoglobulins), biotin (which forms a complex with avidin and streptavidin), and lectin (which forms a complex with carbohydrate deter-

minants, e.g. receptors). In this case, the complex is not in itself directly detectable, necessitating labelling of the substance with which the complexing agent forms a complex. The marking may be performed with any of the labelling substances described above.

- 5 Further, carbohydrates and detectable antibodies may be employed as labels.

In an embodiment of the invention, the diagnostic agent may comprise an immunologically active component of *B. burgdorferi* which is coupled to a bridging molecule coupled to a solid support. The bridging molecule, which is designed to link the solid support and the immunologically active components may be hydrazide, Protein A, glutaraldehyde, carbodiimide, or lysine.

The solid support employed in the diagnostic agent of the invention is e.g. a polymer or it may be a matrix coated with a polymer. The matrix may be of any suitable solid material, e.g. glass, paper or plastic. The polymer may be a plastic, cellulose such as specially treated paper, nitrocellulose paper or cyanogenbromide-activated paper. Examples of suitable plastics are latex, a polystyrene, polyvinylchloride, polyurethane, polyacrylamide, polyvinylacetate and any suitable copolymer thereof. Examples of silicone polymers include siloxane.

The solid support may be in the form of a tray, a plate such as a mitrotiter plate, e.g. a thin layer or, preferably, strip, film, threads, solid particles such as beads, including Protein A-coated bacteria, or paper.

In another aspect, the invention relates to an antibody which is raised against or directed substantially only against a surface antigen as specified above which, as its major immunizing component, comprises a determinant of the OspA polypeptide or an immunological active subsequence thereof. Such an antibody may be a polyclonal or monoclonal antibody.

- For purposes not requiring a high assay specificity, the antibody may be a polyclonal antibody. When a higher specificity is desired, the antibody is preferably a monoclonal antibody. Usually, the use of a monoclonal antibody provides a higher precision and accuracy of the assay, at the same time possibly requiring less time to perform. A mixture of two or more different monoclonal antibodies may be employed as this may increase the detection limit and sensitivity of the test. The monoclonal antibody may be obtained by use of conventional techniques, e.g. as a result of fusing spleen cells from immunized mice (such as Balb/c mice) with myeloma cells using conventional techniques (e.g. as described by Dalchau et al., 1980 (33)). The fusions obtained are screened by conventional techniques such as binding assays. Antibodies possessing high affinity may be selected for catching techniques.
- 15 Polyclonal antibodies may be obtained by conventional techniques, e.g. by injecting the *B. burgdorferi* preparation into an animal, preferably after the addition of a suitable adjuvant such as Freund's incomplete or complete adjuvant. When the immunogens are protein-containing fractions from *B. burgdorferi* spirochaetes, the animals may be rabbits, mice etc. The animals are bled regularly, for instance at weekly intervals, and the blood obtained is separated into an antibody containing serum fraction, and optionally said fraction is subjected to further conventional procedures for antibody purification, and/or procedures involving use of *B. burgdorferi* fractions.
- 25 The antibody used in the present method is preferably in substantially pure form, e.g. having been purified according to suitable techniques, in order to improve the precision and/or accuracy of the assays of the invention.

In a further aspect, the present invention relates to a method of determining the presence of the *B. burgdorferi* antigen in a sample which method comprises incubating the sample with the antibody defined above and detecting the presence of bound antigen resulting from the incubation. The antibody may be provided with a label as explained above and/or may be bound to a solid support as exemplified above.

The detection of *B. burgdorferi* antigens in a sample may be carried out by using some of the well known ELISA principles, e.g. direct, catching, competitive and double enzyme linked immunosorbent assay. In e.g. an inhibition assay a purified polypeptide preparation of the invention is attached to a solid support (e.g. a polystyrene micro-titer tray); the test solution to be measured is mixed with specific reference antibodies, e.g. the antibodies of the present invention, and this mixture is incubated with the solid support provided with the polypeptide preparation as mentioned above. After sufficient washing, enzyme-labelled antibodies are added, and finally enzyme substrate is applied. For further detailed information of the principles employed in ELISA techniques, see for instance Voller et al., 1979 (52).

More specifically, the method of detecting *B. burgdorferi* antigens may be performed by a method comprising incubating the sample with a first antibody, e.g. a monoclonal antibody as described above, which is coupled to a solid support, and subsequently with a second antibody, e.g. of the type described above, which second antibody is provided with a label. The solid support and the label may be of the types mentioned above.

In another embodiment, the detection of *B. burgdorferi* antigens in a sample may be performed by incubating the sample with an antibody, e.g. of the type described above, which is coupled to a solid support, and subsequently with OspA or an immunologically active part thereof being provided with a label. Alternatively, the antibody coupled to the solid support may be incubated with any of fractions B, C and E of which fractions one or more immunologically active components are provided with a label. The label and the solid support may be of any of the types described above.

In another alternative method of determining *B. burgdorferi* antigens in a sample, the sample is incubated with OspA or one or more immunologically active parts thereof which is/are coupled to a solid support, and then incubated with a suitable antibody provided with a label, e.g. of the type described above. The methods discussed above

may be employed for detecting *B. burgdorferi* antigens in any sample, e.g. in any of the samples discussed above.

In a further aspect, the present invention relates to a diagnostic agent for the detection of *B. burgdorferi* infection in humans and animals, which diagnostic agent comprises a DNA sequence which is homologous to a DNA sequence encoding an immunologically active component of *B. burgdorferi*.

The DNA sequence may be a sequence which encodes any of the immunologically active components of *B. burgdorferi*. Thus, the DNA sequence may be the sequence encoding one of the immunologically active proteins contained in any of the above described fractions B, C and E of *B. burgdorferi*, e.g. a DNA sequence which encodes an immunologically active outer membrane protein from *B. burgdorferi*. Preferably, the DNA sequence is the sequence encoding OspA or a part thereof, which sequence is shown in Fig. 5 and described above.

The diagnostic agent comprising a DNA sequence may be used for the detection of *B. burgdorferi* infections in humans and animals by use of a method which comprises reacting a sample from the human or the animal with the diagnostic agent comprising the DNA fragment and detecting the presence of homologous DNA in the sample. The DNA fragment for this detection may be the DNA fragment shown in Fig. 5 or a part thereof.

The DNA fragment used for this purpose may be provided with a label, e.g. a label of the type described above and may be coupled to a solid support, e.g. of the type described above.

In a particular embodiment of the invention, diagnosis of *B. burgdorferi* infection in humans or animals is performed by use of a DNA probe, and the polymerase chain reaction procedure described by Randall et al., 1985 (21), Randall et al., 1988 (53), and Stoflet et al., 1988 (54) may be employed. The polymerase chain reaction (PCR) is a procedure used for the amplification of DNA present in a sample. The procedure involves the use of two oligonucleotide primers which flank the DNA segment to be amplified. The oligonucleotide primers

may e.g. comprise the flanking regions of the *ospA* gene and may thus be used to amplify the *ospA* gene present in a sample. The oligonucleotide primers hybridize to opposite strands of the DNA sequence to be amplified, and the primers are extended by using DNA polymerase, e.g. the Klenow fragment of *E. coli* DNA polymerase I or another useful DNA polymerase such as the *Taq* DNA polymerase, so as to synthesize a DNA sequence which is complementary to the DNA sequence to which the primers are annealed. Subsequent to the synthesis of these complementary sequences, the DNA synthesized is denatured, e.g. by heating, from the "parent DNA strings", and the parent strings as well as the newly synthesized DNA strings are subjected to a new PCR amplification cycle. In this manner, it is possible to obtain a substantial amplification of specific DNA sequences which are present in a sample. By use of the PCR amplification method, it may be possible to amplify and thus detect the presence of originally very small and undetectable amounts of DNA sequences present in a sample which presence, in the present context, is used as an indication of *B. burgdorferi* infection.

The present invention will now be further described with reference to the accompanying drawings and the following Examples.

The invention is further disclosed in the following with reference to the drawings in which

Fig. 1 shows a flow diagram of the procedure for isolation of fractions A through F of *B. burgdorferi*. The procedure is described in detail in Example 1. The following abbreviations are used: OGP: octyl- β -glucopyranoside; sarcosyl: sodium lauryl sarcosinate; MeOH: 25% methanol in water; SDS: sodium dodecyl sulfate. The numbers refer to incubation temperatures in °C.

Fig. 2 shows the result of a SDS-PAGE analysis of Coomassie brilliant blue-stained proteins of whole-cell and fractionated lysates of *B. burgdorferi* strain B31 (ATCC 35210). Molecular weights (x1000) are

shown to the right. Lane 1 is fraction F, lane 2 is E, lane 3 is D, lane 4 is C, lane 5 is B, lane 6 is molecular weight standards, and lane 7 is whole-cell *B. burgdorferi* Connecticut strain No. 2591. The SDS-PAGE analysis is described in further detail in Example 1. The gel was run for 5 hours and 20 minutes at 95-280 V. The acrylamide concentration was 10%.

Fig. 3a shows the result of a SDS-PAGE analysis of Coomassie brilliant blue-stained proteins of fractionated lysate of *B. burgdorferi* strain ACA-1 (2). Molecular weights (x1000) are shown to the right.

Lane 1 and 5 are molecular weight standards, lane 2 is fraction E, lane 3 is fraction C, and lane 4 is fraction B. The gel was run for 15 hours and 15 minutes at 74 V. The acrylamide concentration was 15%.

Fig. 3b shows the result of a comparative SDS-PAGE analysis of Coomassie brilliant blue stained proteins of fractionated lysates of *B. burgdorferi* strains B31 and ACA-1. Lane 1 and 8 are molecular weight standards, lane 2 is fraction C of B31, lane 3 is fraction C of ACA-1, lane 4 is fraction E of B31, lane 5 is fraction E of ACA-1, lane 6 is fraction B of B31 and lane 7 is fraction B of ACA-1. The gel was run for 16 hours and 30 minutes at 74 V. The acrylamide concentration was 15%.

Fig. 4 shows the plasmid pTRH32 from which the hybrid plasmid pTRH44 used for nucleotide sequencing of the *OspA* gene of *B. burgdorferi* is produced. The sequencing strategy is depicted. The indicated DNA fragments were cloned into a M13 phage as described in Example 2 and direction of sequencing of the strand is shown by arrows underneath the restriction map. The open box in the plasmid DNA represents pBR322 DNA and the filled-in boxes in the pTRH44 plasmid represent Tn5 DNA. The recognition sites for the endonucleases *HpaI* (Hp), *AhaIII* (A), *HaeIII* (Ha), *PstI* (P), *HindIII* (H), *EcoRI* (E), *ScaI* (S), *SphI* (Sp) and *SalI* (Sl) are indicated.

Fig. 5 shows the nucleotide sequence of the *OspA* structural gene and its upstream 5'-flanking region as well as the amino acid sequence of *OspA* as deduced from the nucleotide sequence of *ospA* and is further

explained in Example 2. The numbers above each line refer to the amino acid position, whereas numbers below the sequence refer to the nucleotide position. The promoter regions P1 and P2 are indicated by horizontal lines. The respective -35 and -10 regions are also shown.

5 The ribosomal binding sites (RBS) are shown by a horizontal line and bold lettering. The start of the OspA protein is indicated and the stop codon is marked by an asterisk.

Fig. 6 shows a hydropathic index of OspA from amino acid 1 to amino acid 273 as determined by computer analysis according to Kyle et al.,
10 1982 (20). The OspA sequence is represented on the X axis while the hydropathic index is represented on the Y axis. A positive hydropathic index indicates a hydrophobic amino acid whereas a negative hydropathic index indicates a hydrophilic amino acid. The index reveals that the N-terminal end of OspA is highly hydrophobic. Compu-
15 ted using an interval of 9 amino acids. (Gravy = -5).

Fig. 7 shows a hydrophilicity profile of protein sequence OspA resulting from computer analysis according to Hopp et al., 1981 (34). The OspA sequence is represented on the X axis and the degree of hydrophilicity is represented on the Y axis. The most hydrophilic region
20 is found around amino acid 54. Computed using an average group length of 6 amino acids.

Fig. 8 shows a curve of the charge of protein OspA as a function of the pH (from 0 to 14) as determined by computer analysis of the deduced amino acid sequence of the OspA protein using the pC/gene
25 programme by Genofit SA, Geneva, Switzerland.

Fig. 9 shows the amino acid composition of the deduced OspA sequence as determined by computer analysis according to Harr et al., 1986 (37).

Figs. 10a-10f show the predicted secondary structure of OspA as determined by computer analysis of the deduced OspA amino acid sequence
30 as described by Garnier et al., 1978 (35). The predicted secondary structure is shown on the sequence using conformation codes (Fig. 10a), as a semigraphical output (Fig. 10b) using the symbols descri-

bed in the Figure, and in plots showing the coil conformation (Fig. 10c), the extended conformation (Fig. 10d), the turn conformation (Fig. 10e), and the helical conformation (Fig. 10f), of the OspA sequence.

- 5 Fig. 11 shows a plot of secondary structure curves for the OspA sequence showing the hydrophobicity profile, the charge residues profile, the alpha helix propensity, the beta sheet propensity, and the reverse turn propensity.

- 10 Fig. 12 shows a plot of the beta turn probability profile of the OspA sequence as determined by computer analysis according to Chou et al., 1979 (36).

Fig. 13 shows the position and sequence of the predicted beta turns as revealed by computer analysis of the deduced amino acid sequence of OspA.

- 15 Fig. 14 shows the IgG antibody responses to the *B. burgdorferi* B fraction ELISA in sera from 52 patients with early and late stage Lyme borreliosis. Control sera from 64 healthy individuals were also measured. The cutoff value, calculated from the 64 healthy control sera, is marked by a dotted line in the figure. The experiments
20 leading to the results shown in the figure are described in further detail in Example 5.

Fig. 15 shows a thin-layer chromatographic analysis of lipid extract from ACA-1 fr. B and B-21 fr. V. The thin-layer plate was developed in hexane:diethylether:acetic acid, 80:20:2 by volume. The thin-layer plate was stained with the anisaldehyde reagent.

- 25 Fig. 16 shows a thin-layer chromatographic analysis of lipid extract from ACA-1 fr. B and B-21 fr. V. The thin-layer plate was developed in chloroform:methanol:water, 65:25:4 by volume. The thin-layer plate was stained with the anisaldehyde reagent.

Fig. 17 shows the result of the analysis of SDS-PAGE of fractionated lysate of *B. burgdorferi* strains B31 and ACA-1 by staining with the lectin ConA. Lane 1 is fraction F of B31, lane 2 is fraction E of B31, lane 3 is fraction D of B31, lane 4 is fraction B of B31, lane 5 is fraction F of ACA-1, lane 6 is fraction E of ACA-1, lane 7 is fraction D of ACA-1, lane 8 is fraction BH of ACA-1, lane 9 is a reference containing the glucoproteins transferrin 80kd and ribonuclease B 17kd.

The present invention will now be further described with reference to the following Examples:

MATERIALS AND METHODS

Media

TSM buffer (10 mM Tris, pH 7.4; 150 mM NaCl; 5 mM MgCl₂)

TSEA (10 mM Tris, pH 7.4; 150 mM NaCl; 10 mM EDTA; 0.05% sodium azide)

BSK II medium (Barbour-Stoenner-Kelly medium) [Barbour, A.G. (1984) (25)]

EXAMPLE 1

Preparation of cell fractions

- 5 The procedures for preparing fractions B,C and E of *B. burgdorferi* are summarized in the flow diagram shown in Fig. 1.

Two liters of BSK II medium containing approximately 10^{11} cells of *B. burgdorferi* (ATCC 35210) in late log phase of growth were harvested by centrifugation in a high speed Beckman J221 centrifuge at 9,000
10 x g for 20 minutes at 20°C and washed once with TSM buffer. The resulting pellet was resuspended in 10 ml of TSM buffer and placed on ice. After 15 minutes, 2.4 ml of 10% octyl- β -D-glucopyranoside (OGP; Calbiochem, San Diego, Ca) in TSEA were added. The cell suspension was incubated at 37°C for 1 hour. The resultant cell lysate was
15 centrifuged at 48,000 x g for 30 minutes at 25°C. A clear OGP supernatant (S37) and an OGP-insoluble white pellet (P37) were obtained. The supernatant was then incubated at 56°C for 30 minutes. The flocculent white precipitate (P56) formed after the heating was separated from soluble constituents (S56) by centrifugation at 48,000 x g for
20 30 minutes at 37°C. The original pellet (P37) was washed by resuspension in 10 ml of TSEA, centrifuged at 48,000 x g for 5 minutes and suspended in 10 ml of 1% sodium lauryl sarcosinate (Sarkosyl*) in TSEA and incubated at 37°C for 1 hour and then at 20°C for 15 hours. The P56 fraction was treated in the same way as P37. The P37 suspension
25 remained opalescent, while the P56 fraction cleared when incubated in Sarkosyl.* Both fractions were centrifuged at 48,000 x g for 30 minutes at 25°C. There was a large translucent Sarkosyl*-insoluble pellet (P37-p) and a clear supernatant (P37-s) in the P37 tube. In the P56 tube, there was no discernible pellet; only the supernatant was
30 saved. The P37-s and P56-s fractions were each dialyzed against 25% methanol in glass-distilled water at 20°C. The contents of the dialysis bags (Bethesda Research Laboratories) were lyophilized, and P37-s and P56-s fractions that were recovered were designated fraction F

* = Trade-marks

and fraction E, respectively. Fraction S56 was passed through a 0.45 micron nitrocellulose filter (Millipore low protein binding filter) and then dialyzed against glass-distilled water at 4°C. The S56 precipitate that formed in the dialysis bag was recovered by centrifugation (48,000 x g for 30 minutes at 25°C). The water-insoluble pellet was designated fraction B and the water-soluble supernatant was designated fraction C. Both fractions were lyophilized. Fraction P37-p was resuspended in 10 ml of 1% Sarkosyl^{*} in TSEA and incubated for 1 hour at 37°C. This suspension was then centrifuged at 48,000 x g for 30 minutes at 25°C. The supernatant was discarded. The pellet was resuspended in 2% SDS in TSEA and incubated at 65°C for 30 minutes. The suspension was then centrifuged (48,000 x g for 30 minutes at 25°C). The pellet was designated fraction A and was washed in glass-distilled water, whereas the supernatant (designated fraction D) was dialyzed against 25% methanol. Both fractions were lyophilized. There were insufficient amounts of fraction A produced for extensive testing. This fraction was therefore not used.

To reconstitute the fractions for use as antigens, 100 µg of lyophilized extracts were each mixed with 1.0 ml of PBS containing 0.05% Triton X-100^{*} (Bio-Rad, Richmond, Ca). The protein content was determined using a commercially available assay (Bio-Rad, Richmond, Ca); values ranged from 18 µg/ml (fractions B and E) to 28 µg/ml (fraction C). Solutions of fraction B required three 15-sec bursts using a Biosonic sonicator (Bronwill Scientific, Rochester, N.Y.) at a setting of 60% and pipette washing of this material to obtain adequate suspensions. Similarly, fractions B, C, E, F, D and A of *Borrelia burgdorferi* spirochaetes of the strain ACA-1 described by Åsbrink et al., 1985 (18) were obtained.

* = Trade-marks

Determination of protein content by SDS-PAGE

To determine the protein content of preparations of whole cells and the fractions obtained above of *Borrelia burgdorferi* strains B31 and ACA-1, the preparations were analyzed by polyacrylamide gel electrophoresis (PAGE). The preparations were prepared as follows: After three washings in phosphate-buffered saline containing 5 mM MgCl₂ (pH 6.4), the whole cell spirochaetes and the fractions were suspended in

distilled water. The amount of protein in the suspensions was determined using a commercially available assay (Bio-Rad, Richmond, Ca). Incubation buffer (5% 0.2 M Trizma base neutralized with H_3PO_4 (pH 6.8), 1% SDS, 1% mercaptoethanol, 48% urea in distilled water) was added in an equal volume to the suspensions to give a final concentration of 0.85 mg of protein per ml. The samples were boiled for 5 minutes, and 10 to 25 μ l were subjected to SDS-PAGE in a Hoefer SE 600 Vertical Gel Unit. The protein band pattern obtained for B31 is shown in Fig. 2, the pattern for ACA-1 (fractions B, C and E) is shown in Fig. 3a, and Fig. 3b shows a comparative analysis of fractions B, C and E of strains B31 and ACA-1.

For B31, the acrylamide concentration was 10%. The gels were stained with Coomassie brilliant blue R-250 (Sigma) and included the following molecular weight standards: α -chymotrypsinogen (25,700), ovalbumin (43,000), bovine serum albumin (68,000), and phosphorylase B (97,400) (Bethesda Research Laboratories, Inc., Gaithersburg, Md).

For ACA-1, the acrylamide concentration was 15%. The gels were stained with Coomassie brilliant blue R-250 (Sigma) and included the following molecular weight standards: α -lactalbumin (14,400), soybean trypsin inhibitor (20,100), carbonic anhydrase (30,000), ovalbumin (43,000), bovine serum albumin (67,000), and phosphorylase B (94,000) (Pharmacia, Uppsala, Sweden). These molecular weight standards were also used in the comparative analysis.

The presence of major outer surface proteins (OspA and OspB) of the *B. burgdorferi* strains was further confirmed by testing the above whole cell and fraction preparations by immunoblot analyses according to Barstad et al. (27) against murine monoclonal antibodies (H5332, H3TS, and H6831).

Serologic test enzyme-linked immunosorbent assay (ELISA)

Two isolates of *B. burgdorferi*, the Shelter Island, New York strain B31 (ATCC 35210) and a Connecticut strain (No. 2591) (white footed mouse, Anderson et al., 1983 (11)), were maintained in BSK II medium. Fractionated preparations of spirochaetes were derived from stocks of

the B31 strain, while whole cells used in ELISA are taken from sub-cultures of the Connecticut strain.

Serum samples from persons who had Lyme disease, relapsing fever, yaws, or syphilis were tested against the whole cell or fractions of *B. burgdorferi* in ELISA. The test procedures were essentially as described by Voller et al. (17).

Protein concentrations in preparations of whole cell or fractions of the above strains obtained by the methods outlined above were adjusted by diluting with PBS to 3 μ g and 18 μ g/ml, respectively, to standardize ELISA methods and to ensure optimum reactivity.

Positive and negative (control) antigens were added in alternate rows (50 μ l per well) to 96-well, flat-bottomed, polystyrene plates (Nunc, Denmark). The positive control sera were from persons who had erythema migrans and who lived in areas endemic for Lyme disease. After incubation for 18 to 20 hours at 37°C (at which time the wells were dry), 200 μ l of 0.5% donor horse serum in PBS were added to each well to block binding sites not covered with antigen. Plates were incubated for 1 hour at 37°C and washed three times with PBS-0.05% Tween 20.*

Test sera were diluted in twofold steps starting at 1:80 in a dilution buffer of PBS-0.05% Tween 20 containing 5.0% donor horse serum and 50 μ g of dextran sulfate per ml (analytical grade: ICN Pharmaceuticals, Cleveland, Ohio). Sera were added in 60 μ l volumes to each well, and after 1 hour of incubation at 37°C, the plates were washed four times with PBS-0.05% Tween 20.*

Subsequently, 60 μ l of horseradish peroxidase-conjugated anti-species antisera were added to each well (goat anti-human immunoglobulin, Tago, Inc., Burlingame, Ca) diluted to 1:1000 in dilution buffer. The incubation period for each step was 1 hour at 37°C, followed by four washes with PBS-0.05% Tween 20*.

60 μ l of commercially prepared 2,2'-azino-di-(3-ethyl-benzthiazoline sulfonate) substrate (Kirkegaard and Perry Laboratories, Gaithers-

* = Trade-marks

burg, Md) were added to each well. Plates were then incubated for 60 minutes before determining absorbance values.

Absorbance values (optical densities) of all preparations were recorded at 414 nm by using a microplate photometer (Multiskan; Flow Laboratories, Rockville, Md). For each serum dilution, a net absorbance value (representing the difference in optical densities between positive antigens and PBS) was calculated. Each plate contained a positive serum dilution and a series of known negative control serum dilutions. The average net absorbance values for the known negative serum dilutions were analyzed statistically to determine significant titers for positive reactions. A serum dilution was considered positive if it yielded a net absorbance greater than the total derived by adding three standard deviations to the mean ($[SD \times 3] + \pm$) of the absorbance for the group of negative serum dilutions.

To determine critical regions for positive test results, normal human serum specimens were screened against fractionated (n=22-27 sera tested) and whole cell preparations of *B. burgdorferi* (n=28 sera). The screening was performed for total immunoglobulins and IgG. The results are listed in Table 1. Average net absorption values for samples tested against the fractions ranged from 0.20 to 0.25 and from 0.18 to 0.23 for serum dilutions of 1:320 and 1:640, respectively. In ELISA with whole cell *B. burgdorferi*, cut-off values of 0.26 and 0.17 were recorded. Net absorption values for the positive control sera were usually considerably higher than those listed above, regardless of the antigen used.

Comparative analyses for class-specific IgG antibody revealed differences in specificity and sensitivity when sera were tested with the fractions. The results are listed in Table 2. For example, of the 22 serum specimens from persons who had relapsing fever, yaws, or syphilis that reacted positively to whole cells of *B. burgdorferi*, 7 (32%) remained reactive to fraction B. Only three of 16 samples from patients with syphilis or yaws were positive. In contrast, 30 (91%) of 33 specimens from patients who had Lyme disease and homologous antibody to whole cells of *B. burgdorferi* reacted positively to fraction B. The 3 samples that did not react to fraction B had relatively

low antibody titers (1:640-1:1280) when tested against whole cells. Greater losses of sensitivity were noted in tests with the other fractions.

Serum specimens that were reactive in assays with whole cells of *B. burgdorferi* were reanalyzed in class-specific ELISA with the fractions of *B. burgdorferi* to determine the variability of titration end points. The results are shown in Table 3. Titers for 28 sera differed by 2 fold or less (n=15 samples) or by 4 fold (n=11) when fraction B was coated to the solid phase. Titers for the other two samples differed by 8 fold. Titration end points for 15 samples were usually higher in assays with fraction B than with whole cells. In tests for reproducibility, antibody titers to fraction B differed by 2 fold or less (n=13 samples), 4 fold (n=1), or by 8 fold (n=1) in the second trial. All 12 negative sera were likewise non-reactive in duplicate tests. When results for fractions C, D, E, and F were compared to those of whole cell or to fraction B reactivity (Table 3), 8 or 9 sera were considered positive, respectively. Antibody titers varied by as much as 32 fold.

^b Persons had erythema migrans and one or more later manifestations of Lyme disease.

The sensitivity and reproducibility of assays were monitored daily by including the same positive and negative serum specimens. When new lots of peroxidase-labelled antisera were purchased, procedures were standardized accordingly.

EXAMPLE 2

*Isolation and sequence analysis of the OspA genes**Bacterial strains and plasmids*

Escherichia coli TG1 [*supE*, *thi*, (*lac-pro*), *hsdD5/F'* *traD36*, *proAB*,
5 *lacI*, *lacZ* M15] (Gill et al., 1986 (43)) were used as hosts for M13
growth. pTRH44 is an ampicillin resistant derivative of the vector
pUC9 (44). The pUC plasmid carries an 1,6 kb DNA fragment containing
the gene encoding OspA. The construction of the plasmid pTRH44 is
described in Howe et al., 1986 (39).

10 *Media and culturing conditions*

Cells were grown in L-broth (G. Bertani, 1952 (45)) supplemented with
medium E (Vogel and Bonner, 1956 (40)). Plasmid-containing strains
were grown in media supplemented with ampicillin (100 microgram/ml).
The bacterial cultures were incubated at 37°C while shaking. The *E.*
15 *coli* DH5 (*recA*) (purchased from BRL, Life Technologies, Inc.) was
transformed with pTRH44 after having been made competent by the CaCl_2
method according to Hanahan, 1983 (41).

Isolation of plasmid DNA

Restriction endonucleases, T4 DNA ligase, reverse transcriptase (Life
20 Sciences Inc.), Sequenase^{*} (US Biochemical), and the Klenow fragment
of DNA polymerase I (New England Biolabs and Pharmacia) were used as
recommended by the manufacturers. Plasmid DNA was isolated from an
overnight culture of *E. coli* DH5 harbouring the plasmid pTRH44 by
lysing the cells by the "lysis by boiling"-method according to Mania-
25 tis et al., 1982 (30). The plasmid DNA was digested with *HpaI* and
SalI so as to obtain the 1.6 kb DNA fragment encoding OspA. The
1.6 kb DNA fragment was isolated by agarose gel electrophoresis as
described by Maniatis et al., 1982 (30) and was subjected to further
restriction enzyme cleavage in accordance with the strategy outlined
30 in Fig. 4. The DNA fragments were isolated by using an analytical

* = Trade-marks

electroelutor (International Biotechnologies, Inc.) as recommended by the vendor.

Sequence analysis

The DNA fragments obtained above were ligated into M13 mp18 and mp19
5 vectors (Messing et al., 1982 (44)) and transfected into *E. coli*
strains TG1 by the method described by Hanahan, 1983 (41). The cloned
fragments were sequenced by the dideoxynucleotide chain-termination
method of Sanger et al., 1977 (42). The software developed by Harr et
al., 1986 (37) for VAX^{*} computers (Digital Equipment Corporation) was
10 used to assemble the DNA sequences and to perform the DNA and protein
sequence analyses. The resulting DNA sequence and the amino acid
sequence deduced from the DNA sequence is shown in Fig. 5.

The analysis of the DNA sequence revealed that the Ospa presumably is
encoded by an open reading frame of 819 nucleotides starting at
15 position 151 of the DNA sequence and terminating at position 970 of
the DNA sequence. The corresponding protein encoded by this open
reading frame is a 273 amino acid protein having a molecular weight
of 29,334 kd as predicted from the sequence analysis. No other rea-
ding frames on the DNA fragment could be translated to proteins of
20 any significant length. Besides the presumed TAA-stop codon of the
Ospa gene positioned at nucleotide position 970-972, the isolated DNA
fragment contains 12 bases which presumably separate the Ospa gene
and the Ospb gene which, as described above, are presumed to be
organized within the same operon.

25 Fourteen bases upstream of the presumptive start codon of Ospa at
position 151 is a consensus ribosomal binding site (-AAGGAGA-) (Gold
et al., 1981 (27)). Further upstream from this translational start
point are two regions, P1 and P2. These regions are similar although
not identical to the consensus sequence for sigma-70 promoters found
30 in *E. coli* (Rosenberg and Court, 1979 (28)). An alternative promoter
site closer to the ATG-start codon was also found, this possible
promoter had a spacing between the "-35" and "-10" boxes that was not
in agreement with the optimum spacing favoured by the consensus
sequence. The P1 promoter was found to most closely resemble the

* = Trade-marks

consensus sequence. As mentioned above, the OspA and OspB encoding DNA sequences are found within the same operon located on a linear plasmid in *B. burgdorferi*. The result of the DNA sequencing has revealed that a 12 base pair region separates the *ospA* and *ospB* genes and that the *ospA* gene is located 5' to the *ospB* gene. The twelve base pair region which separates the *ospA* and *ospB* genes follows the TAA-stop codon of the Ospa gene and also contains a ribosome binding site that is similar in sequence to the ribosome binding sequence preceding the Ospa open reading frame.

- 10 Notable features of the sequence upstream of the Osp genes and the P1 and P2 promoters include two closely-spaced direct repeats of the twelve base sequence AACCAAACCTTAA (beginning at positions 13 and 29). A 14-mer palindromic sequence (TTATATTAATATAA) starting at nucleotide 123 surrounds the "-10 regions" of the putative promoters P1 and P2.

15 *Amino acid composition and codon usage*

The deduced amino acid composition of the Ospa protein is shown in Fig. 5 and is not remarkably different from the composition of the proteins of other groups of organisms (Dayhoff et al., 1983 (46)). The estimated total number of amino acid residues of Ospa is 273. Of note, however, is the comparatively high content (15%) of lysine, threonine (11%) and serine (10.5%) calculated on the total amount of amino acid residues in Ospa. Only one cysteine residue was found in Ospa. Ospa is a basic protein with a calculated isoelectric point of 9.5. pH 7.0 Ospa has a predicted charge of +4. The overall amino acid composition is shown in Fig. 9.

The utilization of codons in the Ospa gene was compared with the codon usage in *E. coli*. As expected of an organism with a G+C content of 30% (Hyde and Johnson, 1984 (47)), *B. burgdorferi* has a preference for codons with an A or U in the wobble position.

30 *Sequence analysis of the translated Ospa protein*

The primary structures of the translated protein was analyzed for signal sequences using the method of von Heijne, 1983 (23). A pos-

sible cleavage site in the open reading frame specifying OspA was found between the alanine and cysteine residues at positions 16 and 17.

Thus, the first 16 amino acid residues of OspA presumably constitute the signal sequence of OspA.

Beginning at residue 5 in OspA, the protein has an amino acid sequence which is also found in the corresponding position of OspB. Thus, the following sequence: L-x-x-x-x-L-x-L-A-L-I-x-C is common to the OspA and OspB proteins, in which sequences "x" is a non-charged amino acid residue, "L" is a leucine residue, "A" is an alanine residue, "I" is an isoleucine residue, and "C" is a cysteine residue. A variation of this sequence in which the first two leucines are replaced by isoleucines was found starting at residue 5 of the precursor of another plasmid-specified protein, the β -lactamase of *Staphylococcus aureus* (McLaughlin et al., 1981 (48)). This protein and OspA also share a number of other common features including the N-terminal sequence M-K-K, in which "M" is methionine, and "K" is lysine, asparagines at positions 20 and 28, a serine at position 22, a glutamine at position 26, a valine at position 40, and a lysine at position 46. The *S. aureus* β -lactamase belongs to a group of proteins, the lipoproteins, that are fatty acylated at a cysteine residue in the N-terminus of the processed protein (Wu and Tokunaga, 1986 (49)). This class of proteins have a typical consensus tetrapeptide in their signal peptide (L-z-z-C), where z predominantly represents small, neutral amino acids (Wu et al., 1986 (49)). The OspA and also the OspB proteins show sequence similarity to the consensus sequence of the signal sequence of the lipoprotein precursors in bacteria. OspA as well as OspB have a sequence of L-z-z-C around the suspected peptidase cleavage site. In OspA, the sequence is L-I-A-C while in OspB it is L-I-G-C.

The hydropathicity profile and predicted secondary structure illustrated in Figs. 6 and 10-13 for the OspA protein were found to be similar to the hydropathicity profile seen for other outer membrane proteins (Nikaido et al., 1985 (50)). Although the 16 amino acid signal peptide of OspA is highly hydrophobic, the remainder of the

E

OspA protein contains several hydrophobic regions. These regions were found between amino acids 53 to 56, 72 to 76, 163 to 171, 214 to 226, and 242 to 246. The highest local hydrophilic region of the OspA protein was found around amino acid 46. Similar hydropathicity profile and predicted secondary structure were found for OspB.

When the OspA and OspB proteins were compared, they were found to have 53% overall sequence identity. The greatest degree of similarity between the two proteins was present in the initial one-third and the terminal one-third of the proteins (Fig. 12).

The middle part of each protein showed divergence from one another.

Both Osp proteins were also examined for sequence similarity to other known proteins in the NBRF database using the algorithm of Lipman et al., 1985 (51). With the exception of *S. aureus* β -lactamase this analysis failed to reveal any significant sequence similarity to any other proteins in the database.

EXAMPLE 3

Alternative methods of fractionating B. burgdorferi cells

Example 3a

The procedure outlined in Example 1 for preparing cell fractions was repeated with different detergents in step a), comprising the lysing of *B. burgdorferi* spirochaete cells. The first supernatant (S37) was analyzed by SDS-PAGE to determine which detergents could be used in this step. The following detergents were tested:

the non-ionic detergents, hexyl- β -D-glycopyranoside, heptyl- β -D-glycopyranoside, octyl- β -D-glycopyranoside, nonyl- β -D-glycopyranoside, decyl- β -D-glycopyranoside, dodecyl- β -D-maltoside, MEGA-8 (octanoyl-N-methylglucamide), MEGA-9* (nonanoyl-N-methylglucamide), MEGA-10* (decanoyl-N-methylglucamide) (Calbiochem, San Diego, CA) and Triton X-100* (Sigma Chemical Co., St. Louis, MO),

* = Trade-marks

e

the zwitterionic detergents, Zwittergents^{*} 3-08, 3-10, 3-12, 3-14 and 3-16 (Calbiochem, San Diego, CA), CHAPS^{*} (3-[(3-cholamidopropyl)dimethylammonio]-1-propanesulfonate), CHAPSO^{*} (3-[(3-cholamidopropyl)-dimethylammonio]-2-hydroxy-1-propanesulfonate) (Sigma Chemical Co.,
5 St. Louis, MO),

the anionic detergents, SDS (lauryl sulfate), deoxycholic acid and Sarkosyl^{*} (lauryl sarcosinate) (Sigma Chemical Co., St. Louis, MO).

Similar results were obtained with all detergents with the exception of the following: hexyl- β -D-glycopyranoside, MEGA-8 and Zwittergent^{*}
10 3-08 gave an insufficient solubilization of the spirochaete cells, probably due to their too short carbon chains. Triton X-100^{*} also gave a poor solubilization; SDS and deoxycholic acid gave patterns on the SDS-PAGE indicating a different level of solubilization.

Example 3b

15 The procedure of Example 1 for preparing cell fractions was repeated with different temperatures in the second incubation. The supernatant (S56) was analyzed by SDS-PAGE. The different temperatures tested were 42°C, 50°C and 56°C. Optimum precipitation of proteins in this incubation was obtained at 56°C. Only a low degree of precipitation
20 was obtained at 42°C; at 50°C, a slightly higher degree of precipitation was obtained.

Example 3c

The procedure of Example 1 for preparing cell fractions was repeated with different concentration of OGP in step a), comprising the lysing
25 of *B. burgdorferi* spirochaete cells, and the resulting supernatant (S37) was analyzed by SDS-PAGE. The different concentrations tested were 0.5% and 2%. No differences in solubilization could be detected by SDS-PAGE.

* = Trade-marks

Example 3d

The procedure outlined in Example 1 for preparing cell fractions was repeated with different detergents in step a), comprising the lysing of *B. burgdorferi* spirochaete cells. Fraction B was analyzed for activity in ELISA with different samples of patient serum. The different detergents tested were Zwittergent 3-10 and decyl- β -D-glycopyranoside compared with OGP. No differences in reaction against patient sera in ELISA could be seen with Fraction B prepared with the three different detergents. The results obtained appear from the following table.

		Number of positive in ELISA		
Patient serum	(n)	OGP	DGP	3-10
Normal individuals	(4)	0	0	0
Rheumatoid factor	(4)	0	0	0
Anti nuclear antibody	(2)	0	0	0
Wasserman positive	(3)	0	0	0
Borreliosis	(3)	3	3	3

EXAMPLE 4

Analysis of Fraction B

Example 4a

Qualitative lipid analysis of fraction B was performed using thin layer chromatography. Lipids were extracted from the fraction by addition of 20 volumes chloroform:methanol (2:1 v/w). 10 volumes of 2% (w/v) KH_2PO_4 in water were added, and the phases were allowed to separate. The lower, organic phase was recovered and dried by addition of anhydrous Na_2SO_4 . The extract was filtered and evaporated to near dryness under a stream of N_2 .

20

Neutral lipids were separated by thin layer chromatography on plates coated with Silica gel G^{*} (Merck, Darmstadt, FRG) which were developed in diethylether:hexane:acetic acid 15:84:1 (v/v). Polar lipids were separated on Silica gel H^{*} (Merck, Darmstadt, FRG) plates which were
5 impregnated with carbonate acid and developed in chloroform:methanol:acetic acid:water 25:15:4:1 (v/v). Spots were visualized in iodine vapour. (Kates, M. in Techniques of lipidology (Work, T.S. and Work, E. eds) 1972, North-Holland Publishing Co., Amsterdam). Olive oil, phosphatidyl choline and a mixture of glycerides were used as
10 references. Fraction B prepared from strain ACA-1 was found to contain phospholipids, mono-, di- and tri-glycerides as well as phosphatidyl choline.

Glycolipids were separated on HPTLC plates (Merck, Darmstadt, FRG) which were developed in hexane:diethylether:acetic acid 80:20:2
15 (v/v), Figure 15, or chloroform:methanol:water 65:25:4 (v/v), Figure 16. The plates were stained with the anisaldehyde reagent. Fraction B from both strain ACA-1 and strain B31 were found to contain a number of different glycolipids, including lipids with mono-, di-, and tri-saccharides as well as other sugar moieties.

20 Example 4b

The carbohydrate content of Fraction B from strain ACA-1 and strain B31 was determined by slotblotting samples of the fraction containing 0.07-20 µg protein onto an Immobilon^{*} filter (Millipore/Waters, Bedford, Ma) and staining with Acid Fuchsin (Sigma Chemical Co., St
25 Louis, Mo) reagent. The fraction could be seen to contain approximately 0.1 to 0.5 mg carbohydrate per mg protein, probably including both carbohydrate as glycoproteins as well as glycolipids. The blotting filters were also developed with use of the Lectin-Link^{*} kit (Genzyme, Boston, Ma). Of the lectins used, Concanavalin A (ConA),
30 Ricinus Communis Agglutinin (RCA), Datura Stramonium Agglutinin (DSA) and Wheat Germ Agglutinin (WGA), all four stained Fraction B from both strain ACA-1 and strain B31.

Example 4c

* = Trade-marks

Analysis of glycoproteins in fractions from strains ACA-1 and B31 was performed by SDS-PAGE followed by electroblotting into an Immobilon filter (Millipore/Waters, Bedford, Ma) and thereafter developed with the Lectin-Link kit (Genzyme, Boston, Ma). The lectin ConA bound to a number of proteins in the fractions analyzed as can be seen in Figure 17. Analysis with the lectin WGA gave a similar result. From this it can be concluded that many of the proteins in these fractions are glycolipids.

Figure 17 shows the result of the analysis of SDS-PAGE of fractionated lysate of *B. burgdorferi* strains B31 and ACA-1 by staining with the lectin ConA. Lane 1 is fraction F of B31, lane 2 is fraction E of B31, lane 3 is fraction D of B31, lane 4 is fraction B of B31, lane 5 is fraction F of ACA-1, lane 6 is fraction E of ACA-1, lane 7 is fraction D of ACA-1, lane 8 is fraction B of ACA-1, lane 9 is a reference containing the glucoproteins transferrin 80kd and ribonuclease B 17kd.

EXAMPLE 5

Serologic test enzyme-linked immunosorbent assay based on B. burgdorferi fractions

The experiments were carried out substantially as described in Example 1 above in the section "Serologic test enzyme-linked immunosorbent assay (ELISA)".

Strains and cultivation

The above-discussed strains of *B. burgdorferi*, the Shelter Island, New York strain B31 (ATCC 35210) and the Swedish strain ACA-1 were cultivated and fractionated substantially as described in Example 1 ("Preparation of cell fractions"). Fractions B, D and E were obtained.

Patient sera

Serum samples were obtained from 30 patients with erythema chronicum migrans. The clinical symptoms of these patients and the serologic results of the sera in an ELISA based on whole cell antigen have previously been published (2). 22 patient sera obtained from clinically and serologically verified late stage Lyme borreliosis were tested. Negative control sera were obtained from 64 healthy people from Northern Sweden with no known exposure to Lyme borreliosis. Additional sera were obtained from 11 patients with reactive arthritis, and 13 with mononucleosis. Fifty sera with titers of rheumatoid factor ranging from 1/80 to 1/1280, as determined by the method of Waaler (55), were also analyzed. Furthermore, 70 sera with titers from 1/100 to 1/1600, as determined by an immunofluorescent assay (56) on sections from rat liver, of anti-nuclear antibody (ANA) and 12 Wassermann positive sera were included (57). Seven sera from patients with serologically verified syphilis were also tested.

ELISA methodology

The protein concentration was adjusted for each *B. burgdorferi* fraction obtained above from both strains B31 and ACA-1 by addition of PBS to 6 µg/ml. These fractions were coated to flat-bottom polystyrene microtiter plates (high binding immunoplates; Nunc, Roskilde, Denmark) by adding 50 µl of each suspended fraction to each well. The plates were kept in moist environment and incubated at 37°C overnight. The plates were washed manually, and 100 µl of serum diluted 1:200, 1:500, or 1:1000 in PBS with 1% milk powder (wt/vol) was added to the wells and incubated for 2 hours at 20°C. After washing, 50 µl of alkaline phosphatase conjugated rabbit anti-human immunoglobulin G (IgG) (Dakopatts, Copenhagen, Denmark) diluted 1:250 in PBS was added. The microtiter plates were incubated at 37°C for 2 hours with gentle agitation. The plates were washed and 100 µl of substrate, p-nitrophenyl phosphate (Sigma Chemical Co., St. Louis, MO) in ethanolamine buffer (pH 9.8) with 5 mM MgCl₂ was added. The enzymatic reaction was stopped by the addition of 100 µl of 1M NaOH. The optical density was measured at 405 nm by a microplate photometer (Flow Laboratories, Rockville, MD).

Results

The sera included as negative controls showed little reactivity in the ELISA. The cutoff value was 0.11 using a serum dilution of 1:500. This may partly be due to the antigen used, but may also depend on little exposure of individuals in Northern Sweden to *B. burgdorferi*. The use of these individuals shows that cross-reactivity to the antigens in fraction B seems to be negligible. Despite this, the IgG antibody responses of previously *Borrelia*-infected individuals were similar to those recorded in tests with whole cell *B. burgdorferi*. Thus, this fraction seems appropriate for serologic confirmation of the later stages of Lyme borreliosis. In the ELISA, forty positive Lyme borreliosis sera (30 low titer and 22 high titer sera) were assayed. The cutoff value in these tests was defined as the mean plus three standard deviations ($[SD \times 3] + x$) for sera from 64 persons from Northern Sweden with no known exposure to Lyme borreliosis. The results are seen in Table 4. Fraction B exhibited the highest sensitivity and specificity in this ELISA. Fraction B was further assayed with sera from persons who had had other diseases; these results are shown in Table 5. Ten sera from patients with reactive arthritis and serum specimens which had shown reactivity in tests for rheumatoid factor (49 sera), and Wassermann (10 sera) did not give any significant net absorption in the ELISA based on the B antigen. Among the sera displaying anti-nuclear activity (ANA-positive sera), two out of 70 (3%) had a net absorption above the cutoff value. One out of 13 (15%) sera from mononucleosis patients exceeded the cutoff value in the ELISA.

Out of 30 sera from early borreliosis, 13 (43%) had a net absorption above the cutoff value in the B-ELISA. All high titer sera had a net absorption greater than the cutoff value.

Thus, as stated above, a number of different sera were investigated for false positive reactions or the presence of cross-reactive antibodies to fraction B. This included sera known to be rheumatoid factor positive. These sera may be a problem in different immunosor-

bent assays due to binding of the Fc fragment of the immunoglobulin. It also included sera from patients with acute mononucleosis in which polyclonal activation may occur. Sera displaying anti-nuclear activity were also included. One out of 13 sera from mononucleosis and 2 out of 70 ANA sera exceeded the cutoff value. None of these four sera had a net absorption above 0.2. This rather low cross-reactivity is considered to be acceptable as such sera show cross-reactivity in most immunosorbent assays.

TABLE 4

10 Reactivity of *Borrelia* serum (dilution 1/200) in early and late stage with fractions of *B. burgdorferi* in ELISA

Serum	Fractions								
	B			D			E		
	A ₄₀₅			A ₄₀₅			A ₄₀₅		
15	x±SD	% pos.	n	x±SD	% pos.	n	x±SD	% pos.	n
Early									
stage	0.28±0.18	55	10(18)	0.22±0.16	20	3(15)	0.067±0.031	18	2(11)
Late									
20 stage	1.289±0.38	100	10(10)	0.28±0.19	63	7(11)	0.22±0.093	11	1(9)

TABLE 5

Specificity of *B. burgdorferi* fraction B measured as reactivity of various patient serum samples in ELISA

25	Serum	No. of serum samples tested	Cross reactivity No. (%)	
	Rheumatoid factor	49	0	(0)
	Anti-nuclear antibody	70	1	(1)
30	Wassermann positive	10	0	(0)
	Syphilis	9	0	(0)
	Reactive arthritis	10	0	(0)

The embodiments of the invention in which an exclusive property or privilege is claimed are defined as follows:

1. Immunologically active fraction B of *Borrelia burgdorferi* obtainable by the following steps:
 - a) lysing *B. burgdorferi* spirochaete cells with a mild non-denaturing detergent so as to release outer membrane components from the cells in a non-denatured form, and subsequently subjecting the lysed cells to centrifugation resulting in a first pellet comprising cell wall and flagellar components and a first supernatant comprising outer membrane components,
 - b) incubating the first supernatant from step a) at 56°C for 30 minutes followed by centrifugation so as to obtain a second pellet comprising fraction E and a second supernatant,
 - c) subjecting the second supernatant from step b) to filtration and
 - (i) dialyzing the supernatant against an aqueous medium with a low ionic strength or
 - (ii) subjecting the supernatant to ultrafiltrationso as to substantially remove the mild non-denaturing detergent and complex *B. burgdorferi* derived cell components in the dialysis bag in the case of (i) or in the filtrate resulting from the ultrafiltration in the case of (ii),
 - d) centrifugating the contents of the dialysis bag so as to obtain a third pellet comprising fraction B and a third supernatant comprising fraction C,

the fraction B being substantially free from cell wall and flagellar components of *B. burgdorferi* and being substantially free from sodium dodecyl sulfate

and being capable of reacting with at least about 85% of sera from patients with Lyme disease, but with not more than about 20% of sera of syphilitic patients.

2. An immunologically active fraction of *B. burgdorferi* antigens according to claim 1 having substantially the same reactivity with sera from patients with Lyme disease as that of whole cells of *B. burgdorferi*, but with substantially less reactivity with sera from syphilitic patients.

3. Immunologically active fraction B according to claim 1 of *B. burgdorferi* spirochaetes of New York strain B31 (ATCC 35210), wherein the fraction is characterized by the following protein bands, expressed as molecular weight in kilodaltons (kd), in a sodium dodecyl sulfate polyacrylamide gel containing 10% by weight of sodium dodecyl sulfate polyacrylamide after electrophoresis at 95-280 V for 5 hours 20 minutes and staining with Coomassie brilliant blue R-250:

Fraction B: 20, 21, 29, 31, 34, 39, 59, 66, 68, 85 kd.

4. Immunologically active fraction B according to claim 3, which comprises the 31 kd and 34 kd proteins, but not flagellin.

5. Immunologically active fraction B according to claim 1 of *B. burgdorferi* spirochaetes of strain ACA-1, the fraction being characterized by the following protein bands (expressed as molecular weight in kilodaltons (kd)) in a sodium dodecyl sulfate polyacrylamide gel (containing 10% by weight of sodium dodecyl sulfate polyacrylamide) after electrophoresis at 74 V for 15 hours 15 minutes and staining with Coomassie brilliant blue R-250 under the conditions specified in Example 1:

Fraction B: 13, 15, 19, 23, 24, 25, 28, 30, 32, 36, 38, 41, 47, 50, 59, 68 kd

6. A method of preparing fraction B of *B. burgdorferi* as defined in any one of claims 1 to 5, which comprises the following steps:

a) lysing *B. burgdorferi* spirochaete cells with a mild non-denaturing detergent so as to release outer membrane components from the cells in a non-denatured form, and subsequently subjecting the lysed cells to centrifugation resulting in a first pellet comprising cell wall and flagellar components and a first supernatant comprising outer membrane components,

b) incubating the first supernatant from step a) at 45° to 65°C for 30 minutes followed by centrifugation so as to obtain a second pellet comprising fraction E and a second supernatant,

c) subjecting the second supernatant from step b) to filtration and

(i) dialyzing the supernatant against an aqueous medium with a low ionic strength or

(ii) subjecting the supernatant to ultrafiltration

so as to substantially remove the mild non-denaturing detergent and complex *B. burgdorferi* derived cell components in the dialysis bag in the case of (i) or in the filtrate resulting from the filtration in the case of (ii),

d) centrifugating the contents of the dialysis bag so as to obtain a third pellet comprising fraction B and a third supernatant comprising fraction C.

7. A method according to claim 6, wherein the mild non-denaturing detergent used in step a) is a non-denaturing water-dialysable detergent selected from the group consisting of a non-ionic, a zwitterionic and an anionic detergent.

8. A method according to claim 7, wherein the mild non-denaturing detergent is octyl- β -D-glucopyranoside (OGP).

9. A method according to any one of claims 6 to 8, wherein the lysis with the detergent is performed at a temperature in the range of about 20-60°C.
10. A method according to claim 9, wherein the lysis with the detergent is performed at a temperature in the range of about 25-50°C.
11. A method according to claim 10, wherein the lysis with the detergent is performed at a temperature in the range of about 30-40°C.
12. A method according to claim 11, wherein the lysis with the detergent is performed at a temperature about 37°C.
13. A method according to any one of claims 6 to 12, wherein the concentration of the mild non-denaturing detergent is in the range of about 0.1-2%.
14. A method according to claim 13, wherein the concentration of the mild non-denaturing detergent is in the range of about 0.2-1%.
15. A method according to any one of claims 6 to 14, wherein the incubation in step b) is carried out at a temperature in the range of about 50-60°C.
16. A method according to claim 15, wherein the incubation in step b) is carried out at a temperature about 56°C.
17. A method according to any one of claims 6 to 16, wherein the aqueous medium against which the dialysis in step c) is carried out is water.

18. A method according to any one of claims 6 to 18, in which, in step (c), the second supernatant obtained in step b) is subjected to microfiltration, through a membrane with a pore diameter of at the most about 2.0 μm .

19. A method according to claim 18, in which, in step (c), the second supernatant obtained in step b) is subjected to microfiltration through a membrane with a pore diameter of at the most about 0.60 μm .

20. A method according to claim 19, in which, in step (c), the second supernatant obtained in step b) is subjected to microfiltration through a membrane with a pore diameter of at the most 0.45 μm .

21. A method according to claim 20, in which, in step (c), the second supernatant obtained in step b) is subjected to microfiltration through a membrane with a pore diameter of at the most about 0.2 μm .

22. A DNA fragment consisting of

a) the nucleotide sequence encoding OspA protein of *Borrelia burgdorferi* as shown in Fig. 5, or

b) a part of the nucleotide sequence of *Borrelia burgdorferi* as shown in Fig. 5 and hybridizing with a probe which comprises the complementary sequence to the full nucleotide OspA sequence shown in Fig. 5,

said DNA fragment encoding a polypeptide which confers an immune response which is equivalent to the immune response conferred by an OspA protein.

23. A DNA fragment according to claim 22 which encodes an OspA polypeptide or encodes a subsequence thereof, said DNA fragment or

subsequence thereof encoding a polypeptide conferring an immune response which is equivalent to the immune response conferred by an OspA protein.

24. A DNA fragment according to claim 22 or 23 which has the OspA encoding sequence shown in Fig. 5 or a subsequence thereof and which encodes a polypeptide conferring an immune response which is equivalent to the immune response conferred by an OspA protein.

25. A DNA fragment according to any one of claims 22 to 24, which includes a sequence encoding a signal peptide for which there is an amino acid recognition sequence.

26. A DNA fragment according to claims 25, wherein the recognition sequence is L-z-z-C, wherein each z independently from the other designates a small, neutral amino acid.

27. A DNA fragment according to claim 26, wherein the small neutral amino acid of the sequence L-z-z-C is isoleucine or alanine.

28. A DNA fragment according to claim 26, wherein the signal peptide comprises the sequence L-l-x-C in the C-terminal region, and x is a non-charged amino acid residue.

29. A DNA fragment according to claim 28, wherein the signal peptide comprises the sequence L-l-A-C in the C-terminal region.

30. A DNA fragment according to any one of claims 22 to 29, which encodes the 31 kd OspA protein of New York strain B31 (ATCC 35210).

31. A DNA fragment according to any one of claims 22 to 30, which encodes an OspA protein having an amino acid sequence which is identical to the amino acid sequence set forth in Fig. 5.

32. A DNA fragment according to any one of claims 22 to 31, which has an OspA encoding nucleotide sequence identical to the OspA encoding nucleotide sequence shown in Fig. 5.
33. A DNA fragment which comprises at least one promoter sequence and further comprises a DNA fragment as defined in any one of claims 22 to 32.
34. A fusion DNA fragment comprising, as one fusion fragment, a DNA fragment as defined in any one of claims 22 to 33, the fusion DNA fragment encoding a fusion polypeptide.
35. A fusion DNA fragment according to claim 34, wherein the fusion polypeptide is one capable of being expressed on the surface of a transformed host organism.
36. A non *Borrelia burgdorferi* vector which comprises a DNA fragment as defined in any one of claims 22 to 35.
37. A vector according to claim 36 which is capable of autonomous replication.
38. A vector according to claim 36 or 37 which is a plasmid or a phage.
39. An unicellular host harbouring a vector as defined in any one of claims 36 to 38.
40. An unicellular host according to claim 39, which is a bacterium, selected from *E. coli* or *Bacillus subtilis*.
41. A method for the preparation of an OspA polypeptide or an immunogenic part thereof, the method comprising the steps of

cultivating the unicellular host according to claim 39 or 40 under conditions allowing expression of the DNA fragment as defined in any one of claims 22 to 35, and

harvesting the resulting polypeptide; or

preparing the polypeptide by means of liquid or solid phase peptide synthesis.

42. A method of diagnosing *B. burgdorferi* infection in humans and animals, the method comprising reacting a sample from the human or the animal with a DNA fragment as defined in any one of claims 22 to 35 or a DNA probe or oligonucleotide primer based on the sequence thereof, and detecting the presence of at least part of the DNA sequence shown in Fig. 5 in the sample.

43. A method according to claim 42, which involves the use of a polymerase chain reaction procedure.

44. A live vaccine for the immunization of an animal, including a human being, against Lyme disease, the live vaccine comprising a non-pathogenic microorganism which carries and is capable of expressing a DNA fragment as defined in any one of claims 22 to 35.

45. A vaccine for immunizing a mammal, including a human being, against Lyme disease, the vaccine comprising an immunogenically effective amount of any one or more of fractions B and E as defined in any one of claims 1 to 5 or combinations thereof together with an immunologically acceptable carrier or vehicle.

46. A vaccine for immunizing a mammal, including a human being, against Lyme disease, the vaccine containing an immunologically effective amount of

a substantially pure OspA polypeptide of *Borrelia burgdorferi* or of an immunogenic part thereof, in admixture with an immunologically acceptable carrier or vehicle.

47. A vaccine for immunizing a mammal, including a human being, against Lyme disease, the vaccine containing an immunologically effective amount of at least one OspA polypeptide or an immunogenic part thereof in admixture with an immunologically acceptable carrier or vehicle, where said polypeptide or an immunogenic part thereof is free from other *B. burgdorferi* spirochaete related material.

48. A vaccine according to any one of claims 45 to 47, comprising OspA or an immunogenic part thereof from the *B. burgdorferi* strain B31 (ATCC 35210) having the amino acid sequence set forth in Figure 5 in combination with one or more proteins from other *B. burgdorferi* strains corresponding to OspA from the *B. burgdorferi* strain B31 (ATCC 35210).

49. The vaccine according to claim 48, wherein the part of the OspA polypeptide is an epitope or an antigenic determinant of the OspA polypeptide.

50. The vaccine according to any one of claims 45 to 49, wherein the OspA polypeptide is the 31 kd polypeptide of New York strain B31 having the amino acid sequence set forth in Figure 5.

51. The vaccine according to any one of claims 45 to 50, wherein the carrier or vehicle is selected from macromolecular carriers selected from the group consisting of a polymer, a polysaccharide or a polypeptide.

52. A vaccine according to any one of claims 45 to 51, which additionally comprises an adjuvant.

53. A vaccine according to claim 52, wherein the adjuvant is selected from the group consisting of Freund's complete or incomplete adjuvant, aluminium hydroxide, a saponin, a muramyl dipeptide, and an oil.

54. A vaccine according to any one of claims 45 to 46 or 51 to 53, wherein immunogenically effective components are OspA polypeptides recovered from the fractions B or E, the fractions B and E being obtainable by the following steps

- a) lysing *B. burgdorferi* spirochaete cells with a mild non-denaturing detergent so as to release outer membrane components from the cells in a non-denatured form, and subsequently subjecting the lysed cells to centrifugation resulting in a first pellet comprising cell wall and flagellar components and a first supernatant comprising outer membrane components,
- b) incubating the first supernatant from step a) at 56°C for 30 minutes followed by centrifugation so as to obtain a second pellet comprising fraction E and a second supernatant,
- c) subjecting the second supernatant from step b) to filtration and dialyzing the supernatant against an aqueous medium with a low ionic strength so as to substantially remove the mild non-denaturing detergent and allow *B. burgdorferi* derived cell components to precipitate in the dialysis bag,
- d) centrifuging the contents of the dialysis bag so as to obtain a third pellet comprising fraction B.

55. Use of an immunogenically effective amount of a substantially pure OspA polypeptide of *B. burgdorferi* or an immunogenic part thereof in the preparation of a composition for the immunization against Lyme disease in a mammal, including a human being.

56. Use of an immunologically effective amount of a substantially pure OspA polypeptide of *B. burgdorferi* or an immunogenic part thereof for the immunization of a mammal, including a human being, against Lyme disease.
57. A diagnostic agent for the detection of *B. burgdorferi* antibodies in a sample, which comprises fraction B of *B. burgdorferi* spirochaetes as defined in any one of claims 1 to 5.
58. A diagnostic agent for the detection of *B. burgdorferi* antibodies in a sample, which comprises one or more polypeptides encoded by the DNA fragment as defined in any one of claims 22 to 35, or fraction B as defined in any one of claims 1 to 5, or a combination of one or more of these polypeptides and proteins.
59. A diagnostic agent according to claim 57 or 58 which is provided with a label.
60. A diagnostic agent according to claim 59, wherein the label is a peroxidase.
61. A diagnostic agent according to claim 60, in which the label is a horseradish peroxidase.
62. A diagnostic agent according to any one of claims 57 to 61, which is coupled to a solid support.
63. A diagnostic agent according to claim 62, wherein the solid support is selected from plates, strips, beads, film and paper.
64. A method of determining the presence of *B. burgdorferi* antibodies in a sample, the method comprising incubating the sample with a diagnostic agent

as defined in any one of claims 57 to 63 and detecting the presence of bound antibody resulting from said incubation.

65. A method according to claim 64, wherein the sample is selected from a human or animal body fluid selected from the group consisting of blood, serum, plasma, urine, cerebrospinal fluid, joint fluid and pericardial fluid or from a human or animal tissue, or suspensions or homogenates of these as well as an anthropod tissue.

66. A composition for the passive immunization of an animal, including a human being, against diseases caused by *B. burgdorferi*, which comprises an antibody which is directed against a polypeptide encoded by the DNA fragment as defined in any one of claims 22 to 35 and a suitable carrier or vehicle.

67. Use of an antibody which is directed against a polypeptide encoded by the DNA fragment as defined in any one of claims 22 to 35 for the passive immunization of an animal, including a human being, against diseases caused by *B. burgdorferi*.

68. Use of an antibody which is directed against a polypeptide encoded by the DNA fragment as defined in any one of claims 22 to 35 for the preparation of a composition for the passive immunization of an animal, including a human being, against diseases caused by *B. burgdorferi*.

Fig. 13

POSITION AND SEQUENCE OF PREDICTED BETA-TURNS

Done on sequence OSPA.

DE
OS

Total number of residues is: 273.

Analysis done on the complete sequence.

The symbols used in the following two tables are:

$p(t)$: the probability of bend occurrence

[$p(t) = f(1)*f(2)*f(3)*f(4)$].

$\langle Pt \rangle$, $\langle Pa \rangle$ & $\langle Pb \rangle$: the average conformational potential for the tetrapeptide to respectively be in the beta-turn, alpha-helix and beta-sheet conformation.
