A system for designing a therapy or for treating a gastrointestinal disorder or a condition associated with excess weight in a subject comprising at least one electrode configured to be implanted within a body of the patient and placed at a vagus nerve, the electrode also configured to apply therapy to the vagus nerve upon application of a therapy cycle to the electrode; an implantable neuroregulator for placement in the body of the patient beneath the skin layer, the implantable neuroregulator being configured to generate a therapy cycle, wherein the therapy cycle comprises an on time during which an electrical signal is delivered, the electrical signal comprising: a) a set of pulses applied at a first selected frequency of about 150-10,000 Hz, wherein each pulse of the set of pulses has a pulse width of at least 0.01 milliseconds and less than the period of the first selected frequency.
NEURAL MODULATION DEVICES AND METHODS

This application is being filed on 8 June 2011, as a PCT International Patent application in the name of EnteroMedics Inc., a U.S. national corporation, applicant for the designation of all countries except the US, and Katherine S. Tweden, a citizen of the U.S., Jonathan J. Waataja, a citizen of the U.S., Adrianus P. Donders, a citizen of the Netherlands, and Mark B. Knudson, a citizen of the U.S., applicants for the designation of the US only, and claims priority to U.S. Provisional Patent Application Serial No. 61/353,850, filed June 11, 2010, which application is incorporated herein by reference.

BACKGROUND OF THE INVENTION

1. Field of the Invention

This invention pertains to devices and methods for neuromodulation for gastrointestinal disorders and conditions associated with excess weight.

2. Background

Obesity and other eating disorders are serious health conditions that lead to increased morbidity and mortality. Over the last decade, the prevalence of obesity has increased more than 80%, representing an estimated 43 million adults in 2002. (Mokdad AH, et al, The spread of the obesity epidemic in the United States, 1991-1998. JAMA 1999;(282):1519-22). In terms of mortality, an estimated 280,000 to 325,000 adults in the United States die each year from causes related to obesity. (Allison DB et al, Annual deaths attributable to obesity in the United States. JAMA 1999; 282:1530-8). More importantly, excess weight has been positively correlated with years of life lost. (Fontaine ICR et al., Years of life lost due to obesity. JAMA 2003;(289):187-93).

In addition to mortality, substantial morbidity is associated with obesity. For example, in 2000, the total cost of obesity in the United States was estimated to be $117 billion ($61 billion in direct medical costs, $56 billion in indirect costs). (U.S. Department of Health and Human Services. The Surgeon General’s call to action to prevent and decrease overweight and obesity. Rockville (MD): U.S. Department of Health and Human Services, Public Health Service, Office of the Surgeon General;
2001). An estimated 9.1% of annual medical spending in the United States is attributed to overweight and obesity — a figure that rivals medical costs attributable to cigarette smoking. In addition, many other conditions are found in patients that have excess weight including hypertension and diabetes.

Thus, there remains a need to develop effective treatments for gastrointestinal conditions and conditions associated with excess weight.

**SUMMARY**

This disclosure is directed to systems and methods for treating gastrointestinal disorders and/or a condition associated with excess weight in a subject. Conditions associated with excess weight include obesity, metabolic syndrome, type II diabetes, prediabetes, hypertension, bulimia, compulsive eating, and gall bladder disease. Gastrointestinal disorders include gastrointestinal disorders that can be treated by at least partial down regulation of neural activity on the vagus nerve including inflammatory bowel disease, pancreatitis, and irritable bowel syndrome. Gastrointestinal disorders also include gastrointestinal disorders that can be treated by up-regulation, or at least partial down-regulation of other nerves (e.g. the splanchnic, or celiac nerves), alone, or in combination with up-regulation or at least partial down-regulation of the vagus nerve.

An aspect of the disclosure provides a system for treating a gastrointestinal disorder or a condition associated with excess weight of a subject comprising at least one electrode configured to be implanted within a body of the patient and placed at a vagus nerve, the electrode also configured to apply therapy to the vagus nerve upon application of a therapy cycle to the electrode; an implantable neuroregulator for placement in the body of the patient beneath the skin layer, the implantable neuroregulator being configured to generate a therapy cycle, wherein the therapy cycle comprises an electrical signal comprising: a set of pulses applied at a first selected frequency of about 150-10,000 Hz, and wherein each pulse of the set of pulses has a pulse width of at least 0.01 milliseconds and less than the period of the first selected frequency.

In other embodiments, the therapy cycle comprises at least one electrical signal that comprises a pulse or set of pulses that have a first selected frequency of about 150 Hz or greater; and a total amount of charge delivered to the nerve of about
5 microcoulombs to 200,000 microcoulombs during the therapy cycle. In embodiments, the therapy cycle is a low charge therapy cycle.

Another aspect of the disclosure provides methods for selecting a therapy cycle for an implantable device in a subject. In one embodiment, the method comprises selecting parameters for a therapy cycle for an implantable device in a subject comprising: selecting parameters of a therapy cycle, wherein the therapy cycle comprises an electrical signal comprising: i) a set of pulses applied at a first selected frequency of about 150-10,000 Hz, and wherein each pulse of the set of pulses has a pulse width of at least 0.01 milliseconds and less than the period of the first selected frequency; communicating the selected parameters to the implantable device comprising the system of claim 1; and determining the amount of actual therapy delivered over a time period and adjusting the parameters of the therapy cycle to achieve delivery of at least 6 hours of treatment or adjusting the parameters of the therapy cycle or both to increase the amount of excess weight loss, to affect the blood pressure, and/or diabetes of the subject.

Another aspect of the disclosure provides a method of treating a gastrointestinal disorder or a condition associated with excess weight in a subject comprising applying an electrode to a vagus nerve at a location below vagal innervation of the heart; applying a therapy cycle to the vagus nerve, wherein each therapy cycle comprises a high frequency electrical signal having a first selected frequency of at least 150 Hz, a low frequency electrical signal having a second selected frequency of less than 150 Hz, an on period of at least 30 seconds, and an off period, wherein the off period is selected to allow at least partial recovery of neural activity. In some embodiments, the method further comprises administering an agent that treats the gastrointestinal condition, affects weight loss, blood pressure, or diabetes. Agents that affect weight loss include but are not limited to agents that enhance the sensation of satiety, agents that decrease appetite, agents that block the absorption of fat or other nutrients, agents that inhibit enzymes that digest fat, agents that are thermogenic, or combinations thereof.

**BRIEF DESCRIPTION OF THE DRAWINGS**

FIG. 1 is a schematic illustration of an alimentary tract (GI tract plus non-GI organs such as the pancreas and liver) and its relation to vagal and enteric innervation;
FIG. 2 is the view of FIG. 1 showing the application of an electrode to the vagus nerve;

FIG. 3 is a schematic representation of an exemplary implantable system configuration for a gastro-intestinal treatment involving applying an electrical signal to a vagus nerve;

FIG. 4 is a schematic representation of a patient’s stomach shown partially in section and illustrating a representative placement of anterior and posterior vagus nerves with respect to the anatomy of the stomach and diaphragm;

FIG. 5 illustrates a neuroregulator, leads and placement of anterior and posterior electrodes on the vagus nerve.

FIG. 6a-c illustrate examples of a therapy cycle delivered to the vagus nerve, a) shows a therapy cycle with an electrical signal having a frequency of about 150 to 10,000 Hz with a pulse width of at least 0.01 milliseconds and less than the period of the selected frequency; b) shows a therapy cycle with an electrical signal having a first selected frequency of about 150 to 10,000 Hz with a pulse width of at least 0.01 milliseconds and less than the period of the selected frequency followed by an electrical signal having a second selected frequency of about 1 to 150 Hz with a pulse width of at least about 0.05 microseconds but less than the period of the second selected frequency; and c) shows a therapy cycle with an electrical signal having a frequency of about 150 to 10,000 Hz with a pulse width of at least 0.01 milliseconds and less than the period of the selected frequency applied in a series of short bursts with a delay period between each burst.

**DETAILED DESCRIPTION**

A. **Description of Vagal Innervation of the Alimentary Tract**

FIG. 1 is a schematic illustration of an alimentary tract (GI tract plus non-GI organs such as the pancreas and gall bladder, collectively labeled PG) and its relation to vagal and enteric innervation. The lower esophageal sphincter (LES) acts as a gate to pass food into the stomach S and, assuming adequate function of all components, prevent reflux. The pylorus PV controls passage of chyme from the stomach S into the intestines I (collectively shown in the figures and including the large intestine or colon and the small intestine including the duodenum, jejunum and ileum). The biochemistry of the contents of the intestines I is influenced by the
pancreas P and gall bladder PG which discharge into the duodenum. This discharge is illustrated by dotted arrow A.

The vagus nerve VN transmits signals to the stomach S, pylorus PV, pancreas and gall bladder PG directly. Originating in the brain, there is a common vagus nerve VN in the region of the diaphragm (not shown). In the region of the diaphragm, the vagus VN separates into anterior and posterior components with both acting to innervate the GI tract. In FIGS. 1, and 2, the anterior and posterior vagus nerves are not shown separately. Instead, the vagus nerve VN is shown schematically to include both anterior and posterior nerves. The vagus nerve VN contains both afferent and efferent components sending signals to and away from, respectively, its innervated organs.

In addition to influence from the vagus nerve VN, the GI and alimentary tracts are greatly influenced by the enteric nervous system ENS. The enteric nervous system ENS is an interconnected network of nerves, receptors and actuators throughout the GI tract and pancreas and gall bladder PG. There are many millions of nerve endings of the enteric nervous system ENS in the tissues of the GI organs. For ease of illustration, the enteric nervous system ENS is illustrated as a line enveloping the organs innervated by the enteric nervous system ENS. The vagus nerve VN innervates, at least in part, the enteric nervous system ENS (schematically illustrated by vagal trunk VN3 which represents many vagus-ENS innervation throughout the gut). Also, receptors in the intestines I connect to the enteric nervous system ENS. Arrow B in the figures illustrates the influence of duodenal contents on the enteric nervous system ENS as a feedback to the secretion function of the pancreas, liver and gall bladder. Specifically, receptors in the intestine I respond to the biochemistry of the intestine contents (which are chemically modulated by the pancreao-biliary output of Arrow A). This biochemistry includes pH and osmolality.

In FIGS 1 and 2, vagal trunks VN1, VN2, VN4 and VN6 illustrate schematically the direct vagal innervation of the GI organs of the LES, stomach S, pylorus PV and intestines I. Trunk VN3 illustrates direct communication between the vagus VN and the ENS. Trunk VN5 illustrates direct vagal innervation of the pancreas and gall bladder. Enteric nerves ENS1-ENS4 represent the multitude of enteric nerves in the stomach S, pylorus PV, pancreas and gall bladder PG and intestines I.
While communicating with the vagus nerve VN, the enteric nervous system ENS can act independently of the vagus and the central nervous system. For example, in patients with a severed vagus nerve (vagotomy—a historical procedure for treating ulcers), the enteric nervous system can operate the gut. Most enteric nerve cells are not directly innervated by the vagus. Gershon, "The Second Brain", Harper Collins Publishers, Inc, New York, N.Y. p. 19 (1998).

B. Therapy Delivery system

The disclosure provides systems for treating a gastrointestinal condition or a condition associated with excess weight comprising a neuroregulator that provides signals to modulate neural activity on the vagus nerve. In an embodiment, a system (schematically shown in Fig. 3) for designing a therapy or for treating such conditions including obesity, hypertension, diabetes or other gastrointestinal disorders includes a neuroregulator 104, and at least one electrode, and in some embodiments, two electrical lead assemblies 106, 106a, each comprising an electrode. In some embodiments, the neuroregulator comprises a power source. In an embodiment, the power source is a secondary (rechargeable) battery or a primary (non-rechargeable) battery. In other embodiments, the neuroregulator does not contain a battery, and power is provided from an external source via radio-frequency energy. In further embodiments, the neuroregulator contains a primary or secondary battery, and can be powered either by the battery, or by power is provided from an external source via radio-frequency energy. The neuroregulator 104 is adapted for implantation within a patient. As will be more fully described herein, the neuroregulator 104 typically is implanted just beneath a skin layer 103.

The neuroregulator 104 is configured to connect electrically to the electrode via one or more electrical lead assemblies 106,106a. In some embodiments, the lead assemblies 106, 106a are electrically connected to the circuitry of the neuroregulator 104 by conductors 114, 114a. Industry standard connectors 122, 122a are provided for connecting the lead assemblies 106, 106a to the conductors 114, 114a. As a result, leads 116, 116a and the neuroregulator 104 may be separately implanted. Also, following implantation, lead 116, 116a may be left in place while the originally placed neuroregulator 104 is replaced by a different neuroregulator. The
neuroregulator 104 generates a therapy cycle including a therapy signal and transmits the therapy signal to the lead assemblies 106, 106a.

The therapy cycle up-regulates and/or down-regulates activity on the nerves of a patient based on the therapy signals provided by the neuroregulator 104. In an embodiment, the lead assemblies 106, 106a include distal electrodes 212, 212a, which are placed on one or more nerves of a patient. For example, the electrodes 212, 212a may be individually placed on the anterior vagal nerve AVN and posterior vagal nerve PVN, respectively, of a patient. For example, the distal electrodes 212, 212a can be placed just below the patient's diaphragm. In other embodiments, however, fewer or more electrodes can be placed on or near fewer or more nerves.

In some embodiments the system further comprises an external charger 101 and/or an external programmer 100.

Another embodiment of a system useful in treating a gastrointestinal disorder or a condition associated with excess weight as described herein is also shown in FIG. 5.

With reference to FIG. 4, a stomach S is shown schematically for the purpose of facilitating an understanding of applying a vagal nerve modulating signal. In FIG. 4, the stomach S is shown with a collapsed fundus F which is deflated due to fasting. In practice, the fundus F can be reduced in size and volume (as shown in FIG. 4) or expanded. The esophagus E passes through the diaphragm D at an opening or hiatus H. In the region where the esophagus E passes through the diaphragm D, trunks of the vagal nerve (illustrated as the anterior vagus nerve AVN and posterior vagus nerve PVN) are disposed on opposite sides of the esophagus E. It will be appreciated that the precise location of the anterior and posterior vagus nerves AVN, PVN relative to one another and to the esophagus E are subject to a wide degree of variation within a patient population. However, for most patients, the anterior and posterior vagus nerves AVN, PVN are in close proximity to the esophagus E at the hiatus H where the esophagus E passes through the diaphragm D.

The anterior and posterior vagus nerves AVN, PVN divide into a plurality of trunks that innervate the stomach directly and via the enteric nervous system and may include portions of the nerves which may proceed to other organs such as the pancreas, gallbladder and intestines. Commonly, the anterior and posterior vagus nerves AVN, PVN are still in close proximity to the esophagus E and stomach (and
not yet extensively branched out) at the region of the junction of the esophagus E and stomach S.

In the region of the hiatus H, there is a transition from esophageal tissue to gastric tissue. This region is referred to as the Z-line (labeled "Z" in the Figures).

Above the Z-line, the tissue of the esophagus is thin and fragile. Below the Z-line, the tissue of the esophagus E and stomach S are substantially thickened and more vascular. Within a patient population, the Z-line is in the general region of the lower esophageal sphincter. This location may be slightly above, slightly below or at the location of the hiatus H.

With reference to FIG. 5, electrodes 212, 212a are shown placed near the esophagus E or proximal portion of the stomach below the diaphragm D and on the anterior and posterior vagus nerves AVN, PVN. In a preferred embodiment, the nerves AVN, PVN are indirectly stimulated by passing electrical signals through the tissue surrounding the nerves. In some embodiments, the electrodes are bipolar pairs (i.e. alternating anode and cathode electrodes). In some embodiments, a plurality of electrodes may be placed overlying the anterior and/or posterior vagus nerves AVN, PVN. As a result, energizing the plurality of electrodes will result in application of a signal to the anterior and posterior vagus nerves AVN, PVN and/or their branches. Of course, only a single array of electrodes could be used with all electrodes connected to an neuroregulator.

The electrical connection of the electrodes to a neuroregulator may be as previously described by having leads (e.g. 106,106a) connecting the electrodes directly to an implantable neuroregulator (e.g. 104). Alternatively, and as previously described, electrodes may be connected to an implanted antenna for receiving a signal to energize the electrodes.

1) **Neuroregulator**

The neuroregulator (Fig. 3) generates electrical signals in the form of electrical impulses according to a programmed regimen. The neuroregulator utilizes a microprocessor and other standard electrical and electronic components, and in some embodiments, communicates with an external programmer and/or monitor by asynchronous serial communication for controlling or indicating states of the device. Passwords, handshakes and parity checks are employed for data integrity. In some
embodiments, the neuroregulator also includes means for conserving energy, which is important in any battery operated device and especially so where the device is implanted for medical treatment of a disorder, and means for providing various safety functions such as preventing accidental reset of the device.

In some embodiments, the neuroregulator 104 initiates the generation and transmission of therapy signals to the lead assemblies 106, 106a. In an embodiment, the neuroregulator 104 initiates therapy when powered by the internal battery 150. In an embodiment, the battery is a secondary (rechargeable) battery or a primary (non-rechargeable) battery. In other embodiments, however, the external mobile charger 101 triggers the neuroregulator 104 to begin generating therapy signals. After receiving initiation signals from the external charger 101, the neuroregulator 104 generates the therapy signals and transmits the therapy signals to the lead assemblies 106, 106a.

Having been programmed by signals from the external mobile charger 101, the neuroregulator 104 generates high and/or low frequency signals to the leads 106, 106a. As will be described, the external mobile charger 101 may have additional functions in that it may provide for periodic recharging of batteries within the neuroregulator 104, and also allow record keeping and monitoring.

While an implantable (rechargeable) power source for the neuroregulator 104 is preferred, an alternative design could utilize an external source of power, the power being transmitted to an implanted module via the RF link (i.e., between coils 102, 105). In this alternative configuration, while powered externally, the source of the specific signals could originate either in the external power source unit, or in the implanted module.

The intermittent aspect of the therapy signal resides in applying the signal according to a prescribed duty cycle. The pulse signal is programmed to have a predetermined on-time in which a train or series of electrical pulses of preset parameters is applied to the vagus branches, followed by a predetermined off-time. Nevertheless, continuous application of the electrical pulse signal may also be effective.

The neuroregulator 104 also may include memory in which treatment instructions and/or patient data can be stored. For example, the neuroregulator 104 can store therapy programs indicating what therapy should be delivered to the
patient. The neuroregulator 104 also can store patient data indicating how the patient utilized the therapy system, reacted to the delivered therapy, health profile of the patient, and dosages and/or side effects of agents that treat the gastrointestinal condition or conditions associated with excess weight.

Signals can be applied at a portion of the nervous system remote from the vagus nerve such as at or near the stomach wall, for indirect regulation of the vagus nerve in the vicinity of the sub-diaphragmatic location. Here, at least one neuroregulator is implanted together with one or more electrodes subsequently operatively coupled to the neuroregulator via leads for generating and applying the electrical signal internally to a portion of the patient's nervous system to provide indirect modulation or down regulation of the vagus nerve in the vicinity of the desired location. Alternatively, the electrical signal may be applied non-invasively to a portion of the patient's nervous system for indirect application of the vagus nerve at a sub-diaphragmatic location.

Features may be incorporated into the neuroregulator for purposes of the safety and comfort of the patient. In some embodiments, the patient's comfort would be enhanced by ramping the application of the signal up during the first two seconds. The device may also have a clamping circuit to limit the maximum voltage (30 volts for example) deliverable to the vagus nerve, to prevent nerve damage. An additional safety function may be provided by implementing the device to cease signal application in response to manual deactivation through techniques and means similar to those described above for manual activation. In this way, the patient may interrupt the signal application if for any reason it suddenly becomes intolerable.

The neuroregulator may be programmed with an external programmer such as a programming wand and a personal computer using suitable programming software developed according to the programming needs and signal parameters which have been described herein. The intention, of course, is to permit noninvasive communication with the electronics package after the latter is implanted, for both monitoring and programming functions. Beyond the essential functions, the programming software should be structured to provide straightforward, menu-driven operation, HELP functions, prompts, and messages to facilitate simple and rapid programming while keeping the user fully informed of everything occurring at each step of a sequence. Programming capabilities should include capability to modify
the electronics package's adjustable parameters, to test device diagnostics, and to store and retrieve telemetered data. It is desirable that when the implanted unit is interrogated, the present state of the adjustable parameters is displayed on the PC monitor so that the programmer may then conveniently change any or all of those parameters at the same time; and, if a particular parameter is selected for change, all permissible values for that parameter are displayed so that the programmer may select an appropriate desired value for entry into the neuroregulator.

Other desirable features of appropriate software and related electronics would include the capability to store and retrieve historical data, including patient code, device serial number, number of hours of battery operation, number of hours of output, and number of magnetic activations (indicating patient intercession) for display on a screen with information showing date and time of the last one or more activations.

Diagnostic testing should be implemented to verify proper operation of the device, and to indicate the existence of problems such as with communication, the battery, or the lead/electrode impedance. A low battery reading, for example, would be indicative of imminent end of life of the battery and need for implantation of a new device. However, battery life should considerably exceed that of other implantable medical devices, such as cardiac pacemakers, because of the relatively less frequent need for activation of the pulse generator of the present invention. In any event, the nerve electrodes are capable of indefinite use absent indication of a problem with them observed on the diagnostics testing.

The device may utilize circadian or other programming as well, so that activation occurs automatically at normal mealtimes for this patient. This may be in addition to the provision for the manual, periodic between meal, and sensing-triggered activation as described above herein. Another form of treatment may be implemented by programming the neuroregulator to periodically deliver the vagal activity modulation at programmed intervals between prescribed normal mealtimes. This will tend to reduce excessive snacking between meals, which may otherwise be of insufficient quantity within a preset time interval to trigger automatic delivery of the therapy. For bulimic, obese, or compulsive overeating patients, the device can be programmed so that when triggered, vagal activity is modulated and the patient's appetite is suppressed by a feeling of fullness (satiety). In some embodiments,
manual activation by the patient is desirable, but because the psychological pattern is difficult to control, the use of circadian programming and detection of overeating by measuring quantity of food consumed during a given interval serves as an important backup in the therapeutic modality.

As discussed above, the neuroregulator may also be activated manually by the patient by any of various means by appropriate implementation of the device. These techniques include the patient's use of an external magnet, or of an external RF signal generator, or tapping on the surface overlying the neuroregulator, to activate the neuroregulator and thereby cause the application of the desired modulating signal to the electrodes. Upon experiencing the compulsive craving, the overweight, obese or bulimic patient can simply voluntarily activate the neuroregulator. If the patient fails to act, the automatic detection of the overeating and consequent application of the necessary therapy will take place through modulation of vagal activity to produce the sensation of satiety.

Neuroregulators, one supplying the right vagus and the other the left vagus may be used. Use of implanted neuroregulators for performing methods as described herein is preferred, but treatment may conceivably be administered using external equipment on an outpatient basis, albeit only somewhat less confining than complete hospitalization. Implantation of one or more neuroregulators, of course, allows the patient to be completely ambulatory, so that normal daily routine activities including on the job performance is unaffected.

2) **External mobile charger**

The optional external charger 101 includes circuitry for communicating with the implanted neuroregulator 104. See Figure 3. In general, the communication is transmitted across the skin 103 along a two-way signal path as indicated by arrows A. Example communication signals transmitted between the external charger 101 and the neuroregulator 104 include treatment instructions, patient data, and other signals as will be described herein. Energy also can be transmitted from the external charger 101 to the neuroregulator 104 as will be described herein.

In the example shown, the external charger 101 can communicate with the implanted neuroregulator 104 via bidirectional telemetry (e.g. via radiofrequency (RF) signals). The external charger 101 shown in FIG. 3 includes a coil 102, which
can send and receive RF signals. A similar coil 105 can be implanted within the
patient and coupled to the neuroregulator 104. In an embodiment, the coil 105 is
integral with the neuroregulator 104. The coil 105 serves to receive and transmit
signals from and to the coil 102 of the external charger 101.

In an embodiment, the external charger 101 can be configured to provide for
periodic recharging of the internal power source 150 of the neuroregulator 104. In
an alternative embodiment, however, the neuroregulator 104 can entirely depend
upon power received from an external source. For example, the external charger
101 can transmit power to the neuroregulator 104 via the RF link (e.g., between coils
102, 105).

The circuitry 170 of the external component mobile charger 101 can be
connected to a first external antenna 102. The antenna 102 communicates with a
similar antenna 105 implanted within the patient and connected to the neuroregulator
104. The external component is configured to send the therapy instructions to the
implantable neuroregulator via the external antenna and the implanted antenna,
Communication between the external component mobile charger 101 and the
neuroregulator 104 includes transmission of therapy cycle parameters and other
signals as will be described.

In other embodiments, the external charger 101 also can provide the
instructions according to which the therapy signals are generated (e.g., pulse-width,
amplitude, and other such parameters). In a preferred embodiment, the external
charger 101 includes memory in which several predetermined programs/therapy
schedules can be stored for transmission to the neuroregulator 104. The external
charger 101 also can enable a user to select a program/therapy schedule stored in
memory for transmission to the neuroregulator 104. In another embodiment, the
external charger 101 can provide treatment instructions with each initiation signal.

In embodiments, the external charger can comprise one or more selectable
operating modules. The selectable operating modules comprise: an operating room
module that is selectable when the external charger is coupled to the first external
antenna, the operating room module being associated with at least a testing operation
to test appropriate positioning of the implantable component within the body; a
therapy delivery module that is selectable when the external charger is coupled to a
second external antenna, the therapy delivery module being associated with therapy
signal generation; and a diagnostic module that is selectable when the external charger is coupled to an external programmer, the programming module being configured to transfer a therapy schedule from the external programmer to the implantable component.

3) External Programmer

Referring to Fig. 3, in embodiments, a system further optionally comprises an external programmer such as a computer (such as a personal computer) or a mobile device (such as a tablet computer, or cellular phone) 100 that can be connected to the external mobile charger 101. With such a connection, a physician can use the programmer 100 to program therapies into the neuroregulator 104 as will be described. In embodiments, the external programmer is configured to provide therapy instructions comprising parameters for each therapy cycle to the external component. In some embodiments, the therapy cycles include parameters that comprise a high frequency therapy signal and a low frequency therapy signal, an on time period and off time period, the off time period selected to allow at least partial recovery of neural activity.

In embodiments, the external programmer is configured to provide therapy instructions that include multiple therapy cycles per treatment period. The external programmer may also provide for one or more than one treatment periods per day or per week.

In embodiments, the external programmer is configured to obtain patient data, wherein the patient data comprises data obtained from the implantable component and patient data concerning the health profile of the patient. A health profile may include the presence or absence of conditions in a subject selected from the group consisting of weight loss, diabetes, hypertension, cardiac condition, liver disorder, a renal disorder and combinations thereof. A health profile may also include age of the patient, the presence of other implantable devices, and medications taken by the patient. Data concerning dosages and/ or side effects of agents that treat the gastrointestinal condition or conditions associated with excess weight may also be obtained and stored on the external programmer. Patient data from the implantable component includes the treatment period of therapy actually delivered to the patient, device therapy data, patient use, and compliance data.
C. Therapy Cycle Parameters

In embodiments, the implantable neuroregulator is configured to deliver one or more therapy cycles. Each therapy cycle includes delivering one or more electrical signals having a set of parameters to a nerve. The electrical signal is delivered to the nerve during an on time. Within that on time, the electrical signal may be delivered as one or more sets of pulses. Each set of pulses can have different parameters such as a different frequency from one another. If an electrical signal is delivered as a set of pulses at a selected frequency, the pulse width of each pulse in the set of pulses is less than the period of the selected frequency. In some embodiments, an electrical signal comprises a set of pulses of two different frequencies. During the on time there may be a delay period between some of the sets of pulses. In embodiments, some of the signals at different frequencies may overlap one another while others are separated from one another by a delay period.

In some embodiments, the delay period between pulses is the same regardless of the frequency of the set of pulses. In other embodiments, the delay period between a set of pulses of one frequency differs from that of a set of pulses at another frequency. While the systems and methods are preferably applied to a vagus nerve, such systems and methods could also be applied to other nerves such as the splanchnic, celiac, and other cranial nerves.

In embodiments, the therapy cycle comprises an electrical signal comprising a set of pulses applied at a first selected frequency of about 150-10,000 Hz, wherein each pulse of the set of pulses has a pulse width of at least 0.01 milliseconds and less than the period of the first selected frequency. The period of the selected frequency is the reciprocal of the frequency in seconds. For example, the period of signal at a frequency of 1000 Hz for a pulse is the reciprocal of the frequency in seconds; 1 millisecond. During the on time, the set of pulses can be applied once or a number of times depending on the desired amount of total charge delivered during the therapy cycle. In embodiments, a therapy cycle delivers about 0.2 coulombs or less of charge. In embodiments, when more than one set of pulses are delivered during an on time at least some of the sets of pulses are separated by a delay period. The delay period can be the same between set of pulses or it can be different.
The first selected frequency can range from about 150 to about 10,000 Hz. In other embodiments, the first selected frequency has a frequency of about 150 to 5000 Hz, preferably about 200 to 5000 Hz, preferably about 250 to 5000 Hz, preferably about 500 to 5000 Hz or preferably about 1000 to 5000 Hz. In an embodiment, the first selected frequency is about 1000 Hz or greater, and has a pulse width of about 0.01 milliseconds to about 0.09 milliseconds. In embodiments, the electrical signal is applied at a frequency that at least partially downregulates activity on the nerve.

In embodiments, the set of pulses have a current amplitude of about 0.1 to 20 mAmps, preferably about 0.1 to 15 mAmps, preferably about 0.1 to 10 mAmps, preferably about 0.1 to 5 mAmps, preferably about 6 to 20 mAmps, preferably about 10 to 20 mAmps, or preferably about 10 to 16 mAmps.

In embodiments, the pulse width of each pulse is about 0.01 milliseconds to about 6 milliseconds, preferably about 0.01 to 4 milliseconds, preferably about 0.01 to 2 milliseconds, preferably about 0.01 to 1 millisecond, preferably about 0.01 to 0.2 milliseconds, or preferably about 0.01 to about 0.1 millisecond. While not meant to limit the scope of the disclosure, it is believed that for an electrical signal delivered at a frequency of 150 Hz or greater, a pulse width of less than 0.01 milliseconds is not effective to change the activity of the nerve. As discussed above, in embodiments, the parameters of the electrical signal at least partially downregulate activity on the nerve.

In embodiments, the pulses in a set of pulses can be monophasic or biphasic or a mixture of monophasic and biphasic. In embodiments, some pulses can be monophasic, in which the pulse width is the simple width of the pulse. In embodiments, some pulses can be biphasic, or comprise more complex waveforms. In these cases, the pulse width is the width of the waveform from beginning to end. The period is the reciprocal of the frequency.

In embodiments, the set of pulses at the first selected frequency can be delivered once or more than once during the on time. If a set of pulses is delivered more than once during the on time, the set of pulses are referred to as a burst of signal. In embodiments, there may be a delay period between the sets of pulses. The delay period between each burst may be the same or different. In an embodiment, more than one burst of pulses having a frequency of at least 150 Hz are delivered.
during an on time. Each burst lasts at least about 26 milliseconds, and each burst is separated by a delay period of at least about 0.3 seconds.

In embodiments, the therapy cycle is a low charge therapy cycle delivering a total charge of 0.2 coulombs or less to the nerve. In embodiments, the total amount of charged delivered in a therapy cycle is about 5 microcoulombs to about 100,000 microcoulombs, more preferably about 10 microcoulombs to about 50,000 microcoulombs, more preferably about 10 microcoulombs to about 10,000 microcoulombs, or more preferably about 10 microcoulombs to about 1000 microcoulombs. In embodiments, the therapy cycle comprising at least one set of pulses having a frequency of at least 150 Hz delivers about 5 microcoulombs of charge or greater. While not meant to limit the scope of the disclosure, it is believed that a low charge therapy cycle as described herein provides for at least partial downregulation of nerve activity while conserving the energy required to power the therapy cycle. In embodiments, the amount of required energy is decreased so that a primary battery rather than a rechargeable battery may be employed in the systems described herein.

In embodiments, the electrical signal that further comprises: a) a set of pulses applied at a second selected frequency of about 1-10,000 Hz, wherein each pulse of the set of pulses has a pulse width of at least 0.05 microseconds and less than the period of the second selected frequency. In embodiments, the second selected frequency is different than the first selected frequency.

The second selected frequency can range from about 1 to about 10,000 Hz. In other embodiments, the second selected frequency has a frequency of about 1 to 1000 Hz, preferably about 1 to 200 Hz, preferably about 1 to 150 Hz, preferably about 1 to 50 Hz, or preferably about 1 to 10 Hz. In an embodiment, the second selected frequency is about 40 Hz or greater, and has a pulse width of about 0.05 microseconds or greater.

In embodiments, the pulse or set of pulses have a current amplitude of about 0.1 to 20 mAmps, preferably about 0.1 to 15 mAmps, preferably about 0.1 to 10 mAmps, preferably about 0.1 to 5 mAmps, preferably about 0.1 to 1 mAmp, preferably about 6 to 20 mAmps, preferably about 10 to 20 mAmps, or preferably about 10 to 16 mAmps.
In embodiments, the pulse width of each pulse is about 0.05 microseconds to about 0.5 second, preferably about 0.1 microsecond to about 0.1 seconds, preferably about 0.5 microseconds to about 0.05 seconds, or preferably about 1 microsecond to .006 seconds.

In embodiments, the pulses in a set of pulses can be monophasic or biphasic or a mixture of monophasic and biphasic. In embodiments, some pulses can be monophasic, in which the pulse width is the simple width of the pulse. In embodiments, some pulses can be biphasic, or comprise more complex waveforms. In these cases, the pulse width is the width of the waveform from beginning to end. The period is the reciprocal of the frequency. If a biphasic pulse is employed the pulse width is the width of the up and down swing, and this sum is less than the period.

In embodiments, the set of pulses at the second selected frequency can be delivered once or more than once during the on time. If a set of pulses is delivered more than once during the on time, the set of pulses are referred to as a burst of signal. In embodiments, there may be a delay period between the sets of pulses. The delay period between each burst may be the same or different. In an embodiment, more than one burst of pulses having a frequency of at less than 150 Hz are delivered during an on time. In embodiments, each burst has about 1 to about 20 pulses, and lasts at least about 10 microseconds, and each burst is separated by a delay period of at least 2.5 milliseconds.

In embodiments, the therapy cycle is a low charge therapy cycle delivering a total charge of 0.2 coulombs or less to the nerve. In embodiments, the total amount of charge delivered in a therapy cycle is about 5 microcoulombs to about 100,000 microcoulombs, more preferably about 10 microcoulombs to about 50,000 microcoulombs, more preferably about 10 microcoulombs to about 10,000 microcoulombs, or more preferably about 10 microcoulombs to about 1000 microcoulombs. In embodiments, the therapy cycle comprising at least one set of pulses having a frequency of less than 150 Hz delivers about 5 microcoulombs of charge or greater.

In embodiments, the set of pulses applied at a first selected frequency of 150 Hz or greater is followed by the set of pulses applied at a second selected frequency of about 1-10,000 Hz. In embodiments, the set of pulses applied at a first selected
frequency of 150 Hz or greater is followed by the set of pulses applied at a second selected frequency of about 1-150 Hz. In other embodiments, the set of pulses applied at a second selected frequency of about 1-10,000 Hz is followed by the set of pulses applied at a first selected frequency of 150 Hz or greater. In yet other embodiments, one or more of the set of pulses may be applied simultaneously or overlapping one another.

In embodiments, an on time of the therapy cycle is at least 30 seconds, more preferably about 30 seconds to 30 minutes, 30 seconds to 20 minutes, 30 seconds to 10 minutes, 30 seconds to 5 minutes, 30 seconds to 2 minutes, and 30 seconds to 1 minute. In embodiments, the therapy cycle has an offtime during which no signal is delivered. In embodiments, the time of the off time is selected to allow at least partial recovery of nerve activity. In embodiments the offtime is at least 30 seconds, more preferably 30 seconds to 30 minutes, 30 seconds to 20 minutes, 30 seconds to 10 minutes, 30 seconds to 5 minutes, 30 seconds to 2 minutes, and 30 seconds to 1 minute. A therapy cycle can comprises one or more on times and one or more offtimes. In an embodiment, the therapy cycle includes 2 minutes of on time, 1 minute of off time, 2 minutes of on time, and 5 minutes of off time. While not meant to limit the scope of the inventive subject matter, it is believed that electrical signals that are delivered with an on time and an off time minimize gastric accommodation, decrease discomfort for the patient, and minimize damage to the nerve.

In embodiments, the neuroregulator is configured to deliver one or more than one therapy cycle in a treatment period. A treatment period ranges from about 6 to 24 hours, preferably 6 to 18 hours, 6 to 12 hours, and 6 to 9 hours. In an embodiment, a treatment period is at least 6 hours.

Exemplary therapy cycles are illustrated in Figures 6 a-c. In figure 6a, the therapy cycle comprises an electrical signal comprising a set of pulses that has a frequency of about 150 to 10,000 Hz, and a pulse width of at least 0.01 milliseconds but less than the period for the selected frequency. In embodiments the electrical signal is a biphasic signal of 1000 Hz or greater with a pulse width of 90 microseconds or greater. While not meant to limit the disclosure, it is believed that a set of pulses that do not fill the entire period can be delivered to the nerve and provide for at least partial downregulation of the activity on the nerve and conserve energy, especially when high frequency signals are delivered to the nerve.
In figure 6b, the therapy cycle comprises an electrical signal comprising a set of pulses that has a frequency of about 150 to 10,000 Hz, and a pulse width of at least 0.01 milliseconds but less than the period for the selected frequency followed by a signal having a second selected frequency of about 1 to 150 Hz with a pulse width of at least 0.05 microseconds but less than the period of the second selected frequency. In embodiments the electrical signal is abiphasic signal of 1000 Hz or greater with a pulse width of 90 microseconds or greater and the signal of the second selected frequency is a biphasic pulse at a frequency of at least 40 Hz with a pulse width of at least 0.05 microseconds.

In figure 6c, the therapy cycle comprises an electrical signal comprising a plurality of a set of pulses that have a frequency of about 150 to 10,000 Hz, and a pulse width of at least 0.01 milliseconds but less than the period for the selected frequency. Each set of pulses is delivered in about 26 milliseconds or greater with a delay period between each set of pulse of 0.3 seconds or greater. The therapy cycle illustrated in this figure shows bursts of signal followed by a delay period.

In embodiments, the therapy cycle comprises an electrical signal comprising: a) a set of pulses that have a frequency of about 150 Hz or greater; and b) a total amount of charge delivered to the nerve of about 5 microcoulombs to about 200,000 microcoulombs during the therapy cycle. While not meant to limit the scope of the invention, it is believed that delivering a low amount of charge during a therapy cycle provides effective treatment while saving energy. In embodiments, the electrical signal is applied at a frequency that at least partially downregulates activity on the nerve.

The total amount of charge delivered during the on time of the therapy cycle can be determined based on the pulse width, current amplitude, frequency and total on time of the signal and are related by the following equation:

\[
\text{Total charge per cycle} = (\text{current amplitude}) \times (\text{pulse width}) \times (\text{frequency}) \times (\text{cycle time})
\]

For a biphasic pulse this equation is divided by 2. In embodiments, the total amount of charge delivered in a therapy cycle is about 10 microcoulombs to about 200,000 microcoulombs, more preferably about 10 microcoulombs to about 100,000 microcoulombs, more preferably about 10 microcoulombs to about 50,000.
microcoulombs, more preferably about 10 microcoulombs to about 10,000 microcoulombs, or more preferably about 10 microcoulombs to about 1000 microcoulombs.

In some embodiments, a therapy cycle further comprises one or more electrical signals having a second selected frequency of less than 150 Hz, and an on time of at least 30 seconds. In embodiments, the frequency of about 150 Hz or greater is different than the second selected frequency. During the on time, both the frequency of about 150 Hz or greater and the second selected frequency signals are delivered to the nerve. In embodiments, the signal having a frequency of about 150 Hz or greater is referred to as a high frequency signal and the second selected frequency signal is referred to as a low frequency signal.

In some embodiments, the frequency of about 150 Hz or greater of the electrical signal ranges from about 150 to 10,000 Hz, about 200 to 8000 Hz, or about 250 to 5000 Hz. In some embodiments, the frequency of about 150 Hz or greater of the electrical signal is about 500 to 1000 Hz. In some embodiments, one or more second selected frequency electrical signal is about 0.5 to 199 Hz, 1 to 150 Hz, or 10 to 100 Hz. In some embodiments, the second selected frequency of the electrical signal is about 10 to 50 Hz. In some embodiments, additional signals at the low frequency will be numbered numerically, e.g., third selected signal, fourth selected signal, etc. While not meant to limit the scope of the disclosure, it is believed that the combination of the high frequency signal and a low frequency signal provides at least a partial downregulation of activity on the nerve.

In embodiments, a signal having a frequency of about 150 Hz or greater comprises a frequency of 200 Hz or greater and include a plurality of charge pulses with pulse widths of about 0.06 to 3000 milliseconds, about 25 to 300 milliseconds, or about 0.06 to 100 milliseconds. In embodiments, a second selected frequency electrical signal can include a plurality of charge pulses with pulse widths of about 0.025 to 25 microseconds or about 0.05 to about 0.5 microseconds. In embodiments, the low frequency signal comprises packets of 1 to 20 pulses, each pulse having a pulse width of 500 nanoseconds or less.

In embodiments, a signal having a frequency of about 150 Hz or greater can comprise a frequency of 200 Hz or greater and have a current amplitude of about 1 to 20 mA, about 1 to 6 mA, or about 1 to 3 mA. In embodiments, a signal having a
frequency of about 150 Hz or greater comprises a frequency of 200 Hz or greater, pulse widths of 60 microseconds or greater.

In embodiments, a second selected frequency signal has a frequency of less than 200 Hz and has a current amplitude of 1 mA or less. In embodiments, a second selected frequency signal comprises a frequency of less than 200 Hz, and a pulse width of about 100 to 500 nanoseconds. In embodiments, a third selected frequency signal comprises a frequency of less than 200 Hz, and a pulse width of 50 to 500 nanoseconds. In embodiments, each signal comprises about 1 to 20 pulses.

In embodiments, the voltage of each signal can vary. In embodiments of the signal having a frequency of about 150 Hz or greater, the voltage is about 1 to 24 volts. In embodiments, the second selected frequency signal has a voltage of about 1 to 15 volts, or 5 to 15 volts. In embodiments, the second selected frequency signal has a voltage of about 0.1 to about 2 volts, or 0.2 volts to 1 volt.

In embodiments, a therapy cycle comprises one or more additional selected frequency electrical signals that are delivered simultaneously, precede, follow, or precede and follow a signal having a frequency of about 150 Hz or greater. In embodiments, a second selected frequency signal, a third selected frequency signal, and a signal having a frequency of about 150 Hz or greater can be delivered simultaneously during an on time of the therapy cycle, each signal having at least one parameter that differs from the other signals. In embodiments, the second selected frequency signal can be applied first followed by the signal having a frequency of about 150 Hz or greater followed by the third selected frequency signal during an on time. In an embodiment, the second and third selected frequency signals are initiated and applied throughout the on time and a signal having a frequency of about 150 Hz or greater is delivered after the initiation of the second and third selected frequency signals. In an embodiment, a third selected frequency signal can be applied first and overlap with a signal having a frequency of about 150 Hz or greater, and then the second selected frequency signal continues in concert with the third selected frequency signal during the on time. In an embodiment, a second selected frequency signal can be applied first and overlap with a signal having a frequency of about 150 Hz or greater, and then the third selected frequency signal is applied during the on time. In embodiments, the second and third selected
frequency signals are applied throughout the on time and the high frequency signal is delivered once during the on time.

In embodiments, an on time for therapy cycle can range from 1 second to 30 minutes or more, 30 seconds to 5 minutes, from 30 seconds to 10 minutes, or from 1 second to 2 minutes. The on time can optionally include a ramp up and a ramp down time of about 2 to 60 seconds. The off times of the electrical signal in the therapy cycle are selected to allow for at least partial recovery of nerve activity. In embodiments, the off times can be selected from about 30 seconds to about 20 minutes, 1 minute to 10 minutes, or 1 minute to 5 minutes.

The implantable component may be configured to generate therapy cycles for a treatment period. The therapy cycles can be continuous or intermittent. In some cases, the treatment period is at least 6 hours. In embodiments, a treatment period is from 30 minutes to 24 hours, 30 minutes to about 12 hours, 30 minutes to 9 hours, 30 minutes to 8 hours, or 30 minutes to 6 hours. In embodiments, a therapy cycle comprises 30 minutes of continuous electrical signal treatment on time with no off times. In some embodiments, treatment periods may be related to the period of time before and after eating of a meal.

**P. Methods**

The disclosure provides a method for manufacturing a system comprising: providing at least one electrode configured to be implanted and placed at a vagus nerve, the electrode is also configured to apply therapy to the vagus nerve upon application of a therapy cycle to the electrode; providing an implantable component for placement in the body of the patient beneath the skin layer, the implantable component being coupled to an implanted antenna and the electrode, and configuring the implantable component to generate a therapy cycle and to transmit the therapy cycle to the electrode. In other embodiments, the method further comprises providing an external charger to be placed above the skin layer and adapted to communicate with the implanted antenna across the skin layer through radiofrequency communication. In some embodiments, the external charger includes a plurality of selectable operating modules, each operating module being associated with a different set of operations available for selection by a user. In embodiments, the method further comprises configuring the external charger to couple to a first
external antenna and to send the therapy instructions to the implantable component via the first external antenna and the implanted antenna; providing an external programmer and configuring the external programmer to a) communicatively couple to the external charger via a second port, b) to provide therapy instructions comprising parameters for each therapy cycle to the external component. In embodiments, the therapy cycle parameters are as described herein in Section C. In an embodiment, the parameters comprise a high frequency and a low frequency signal, the electrical signals having an on time period and off time period, the off time period selected to allow partial recovery of nerve function.

In other embodiments, the disclosure provides a method of selecting parameters for a therapy cycle for an implantable device in a subject comprising: selecting parameters of a therapy cycle to be applied to a vagus nerve, wherein the therapy cycle comprises an electrical signal comprising: a set of pulses applied at a first selected frequency of about 150-10,000 Hz, wherein each pulse of the set of pulses has a pulse width of at least 0.01 milliseconds and less than the period of the first selected frequency; b) communicating the selected parameters to the implantable device comprising the system of claim 1; and c) determining the amount of actual therapy delivered over a time period and adjusting the length of the treatment period to achieve delivery of at least 6 hours of treatment or adjusting the parameters of the therapy cycle or the length of the treatment period or both to increase the amount of excess weight loss, to affect the blood pressure, and/or diabetes of the subject.

In embodiments, the method further comprises selecting the parameters of an electrical signal that comprises: a) a set of pulses applied at a second selected frequency of about 1-10,000 Hz, wherein each pulse of the set of pulses has a pulse width of at least 0.05 microseconds and less than the period of the second selected frequency.

Any of the parameters as described above for the electrical signal of a first selected frequency and a second selected frequency apply to these methods, and can be selected and modified as necessary to increase the amount of excess weight loss, to affect blood pressure, and/or diabetes.

The term "excess weight loss" (EWL) as used herein is determined as follows: ideal body weight is calculated by measuring each subject's height and then
determining the body weight that would result in a BMI of 25.0 for that subject, i.e.,
ideal body weight (kg) = 25 x height² (m). EWL is calculated by dividing weight
loss by excess body weight [(total body weight) - (ideal body weight)] and
multiplying by 100. Thus, EWL% = (weight loss (kg)/excess body weight (kg))
x100.

In embodiments, if the amount of excess weight loss is less than 5%,
parameters and/or treatment periods are adjusted to increase excess weight loss to at
least 10%. Parameters and/or treatment periods may be adjusted once or more than
once in order to reach an excess weight loss of at least 10%. In embodiments, the
method further comprises selecting the parameters of the therapy cycle based on the
starting body mass index of the subject, such as a body mass index of at least 25 or
greater.

In other embodiments, a method of selecting parameters for a therapy cycle
for an implantable device in a subject comprising: selecting parameters of a therapy
cycle to be applied to a vagus nerve to affect blood pressure and/or diabetes of the
subject, wherein the parameters comprise an electrical signal having a first selected
frequency of 200 Hz or greater, an electrical signal having a second selected
frequency of less than 200 Hz, having an on time of at least 30 seconds, and having
an off time that allows at least partial recovery of nerve activity; communicating the
selected parameters to the implantable device using the system described above; and
determining the amount of actual therapy delivered over a time period and adjusting
the treatment period to achieve delivery of at least 6 hours of treatment or adjusting
the parameters of the therapy cycle or both to affect the blood pressure and/or
diabetes of the subject, is provided.

In a further embodiment, the method further comprises selecting the
parameters of the therapy cycle based on the starting blood pressure of the subject,
such as a systolic blood pressure of at least 140 mmHg or a diastolic blood pressure
of 90 mmHg. In embodiments, if the amount of change in systolic blood pressure is
less than 5 mmHg, parameters and/or therapy cycles are adjusted to decrease blood
pressure at least 10 mmHg. Parameters and/or therapy cycles may be adjusted once
or more than once in order to reach a systolic blood pressure of at least 130 mmHg.

In another embodiment, the method further comprises selecting the
parameters of the therapy cycle based on the need to treat diabetes. Patients with
Type 2 diabetes have a fasting plasma glucose of 126 mg/dl or greater; oral glucose tolerance of 200 mg/dl or greater; and/or % of HbA1C of 6.5% or greater. In some cases, the HbA1C percentage is 6-7%, 7-8%, 8-9%, 9-10 %, and greater than 10%. In embodiments, if the amount of change in % of HbA1C is less than 0.5%

parameters and/or therapy cycles are adjusted to decrease % of HbA1C at least 1%. Parameters and/or therapy cycles may be adjusted once or more than once in order to reach a % of HbA1C of at least 7%.

Another aspect of the disclosure provides a method of treating a gastrointestinal disorder or a condition associated with excess weight in a subject comprising: applying an electrode to a vagus nerve at a location below vagal innervation of the heart; applying a therapy cycle to the vagus nerve, wherein each therapy cycle comprises a high frequency electrical signal having a first selected frequency of at least 150 Hz, a low frequency electrical signal having a second selected frequency of less than 150 Hz, an on period of at least 30 seconds, and an off period, wherein the off period is selected to allow at least partial recovery of nerve activity.

Another aspect of the disclosure provides a method of treating a gastrointestinal disorder or a condition associated with excess weight in a subject comprising: applying an electrode to a vagus nerve at a location below vagal innervation of the heart; applying a therapy cycle to the vagus nerve, wherein the therapy cycle comprises an on time during which an electrical signal is delivered, the electrical signal comprising: a) a set of pulses applied at a first selected frequency of about 150-10,000 Hz, wherein each pulse of the set of pulses has a pulse width of at least 0.01 milliseconds and less than the period of the first selected frequency. In embodiments, the methods can involve delivering one or more therapy cycles having a combination of parameters as described herein in section C. In embodiments, the method further comprises a set of pulses applied at a second selected frequency of about 1-10,000 Hz, wherein each pulse of the set of pulses has a pulse width of at least 0.05 microseconds and less than the period of the second selected frequency.

In embodiments, the first selected frequency has a frequency of at least 1000 Hz and the second selected frequency has a frequency of at least 40 Hz. In other
embodiments, the low frequency signal precedes the high frequency signal and/or follows the high frequency signal.

Another aspect of the disclosure provides a method of treating a gastrointestinal disorder or a condition associated with excess weight in a subject comprising: applying an electrode to a vagus nerve at a location below vagal innervation of the heart; applying a therapy cycle to the vagus nerve, wherein the therapy cycle comprises an on time during which an electrical signal is delivered, the electrical signal comprising: a) a set of pulses that have a frequency of about 150 Hz or greater; and b) a total amount of charge delivered to the nerve of about 5 microcoulombs to 200,000 microcoulombs during the therapy cycle.

In embodiments of the methods described herein one or more electrical signals are applied to the vagus nerve. A neuroregulator, as described above, is employed to regulate the application of the signals. The characteristics of the signal include frequency of the signal, location of the signal, and the administration cycle of the signal. Signal characteristics are selected to enhance a sensation of satiety, to modulate intestinal motility and rate of digestion, and/or partial restoration of the nerve activity following discontinuance of the signal, and to minimize enteric accommodation. The parameters for the electrical signal include those as described herein in section C.

Recognition of recovery of endogenous vagal activity (and recognition of the significant variability between subjects) permits a treatment therapy and apparatus with enhanced control and enhanced treatment options. It is expected there will be significant patient-to-patient variability. For example, some patients' responses to electrical signals may not be as dramatic as illustrated. Others may experience recovery slopes steeper or shallower than illustrated. Also, vagal activity in some subjects may remain flat at a reduced level before increasing toward baseline activity. Vagal activity can be measured in any number of ways. For example, quantities of pancreatic exocrine secretion produced per unit time are an indirect measurement of such activity or effects on blood pressure can be measured in hypertensive subjects. Also, activity can be measured directly by monitoring electrodes on or near the vagus. Such activity can also be ascertained qualitatively (e.g., by a patient's sensation of bloated feelings or normalcy of gastrointestinal motility).
1) Location of signal application

Electrodes can be positioned at a number of different sites and locations on or near the vagus nerve. In some embodiments, the electrode is positioned to apply a signal to a branch or trunk of the vagus nerve. In other embodiments, the electrode is positioned to apply a signal to an anterior trunk, posterior trunk or both. The electrode may also be positioned to apply a signal to an organ in proximity to the vagus nerve such as the esophagus or stomach. In some embodiments, the electrode is positioned to apply an electrical signal to the vagus nerve at a location near or distal to the diaphragm of the subject. In other embodiments, up-regulation, or at least partial down-regulation of other nerves (e.g. the splanchnic, or celiac nerves), may be used, alone, or in combination with up-regulation or at least partial down-regulation of the vagus nerve.

For example, FIG. 2 illustrates placement of an electrode. Referring to FIG. 2, the baseline vagal activity is illustrated by the solid line of the proximal vagus nerve segment VNP. The remainder of the vagus and enteric nervous system are shown in reduced thickness to illustrate down-regulation of tone. The pancreo-biliary output (and resulting feedback) is also reduced. In FIG. 2, the electrode is shown high on the vagus relative to the GI tract innervation (e.g., just below the diaphragm), a sole electrode could be placed lower (e.g., just proximal to pancreo/biliary innervation VN5).

In other embodiments, alternative designs for placing electrodes on or near the vagus nerve in a region of the esophagus E either above or below the diaphragm are provided. Two paired electrodes may connect to a pulse generator for bi-polar pacing. In other embodiments, a portion of the vagus nerve VN is dissected away from the esophagus E. An electrode is placed between the nerve VN and the esophagus E. The electrode is placed overlying the vagus nerve VN on a side of the nerve opposite electrode and with electrodes axially aligned (i.e., directly across from one another). Not shown for ease of illustration, the electrodes may be carried on a common carrier (e.g., a PTFE or silicone cuff) surrounding the nerve VN.

Other possible placements of electrodes are described herein US 2005/013 1485 published June 16, 2005, which patent publication is hereby incorporated by reference.
While any of the foregoing electrodes could be flat metal pads (e.g., platinum), the electrodes can be configured for various purposes. In an embodiment, an electrode is carried on a patch. In other embodiments, the electrode is segmented into two portions both connected to a common lead and both connected to a common patch. A flexible patch permits articulation of the portions of the electrodes to relieve stresses on the nerve VN.

2) Therapy Cycle Parameters

Therapy cycle parameters useful in the methods described herein are described above in section C. Such parameters may be adjusted or modified depending on the needs or progress of the patient with regard to weight loss, diabetes, or hypertension.

In embodiments, the implantable component is configured to deliver one or more therapy cycles. Each therapy cycle includes delivering one or more electrical signals having a set of parameters to a nerve.

In embodiments, the therapy cycle comprises an electrical signal comprising a set of pulses applied at a first selected frequency of about 150-10,000 Hz, wherein each pulse of the set of pulses has a pulse width of at least 0.01 milliseconds and less than the period of the first selected frequency. The period of the selected frequency is the reciprocal of the frequency in seconds. For example, the period of signal at a frequency of 1000 Hz for a pulse is the reciprocal of the frequency in seconds; 1 millisecond. During the on time, the set of pulses can be applied once or a number of times depending on the desired amount of total charge delivered during the therapy cycle. In embodiments, a therapy cycle delivers about 0.2 coulombs or less of charge. In embodiments, when more than one set of pulses are delivered during an on time at least some of the sets of pulses are separated by a delay period. The delay period can be the same between sets of pulses or it can be different.

The first selected frequency can range from about 150 to about 10,000 Hz. In other embodiments, the first selected frequency has a frequency of about 150 to 5000 Hz, preferably about 200 to 5000 Hz, preferably about 250 to 5000 Hz, preferably about 500 to 5000 Hz, or preferably about 1000 to 5000 Hz. In an embodiment, the first selected frequency is about 1000 Hz or greater, and has a pulse width of about 0.01 milliseconds to 0.09 milliseconds. In embodiments, the
electrical signal is applied at a frequency that at least partially downregulates activity on the nerve.

In embodiments, the set of pulses have a current amplitude of about 0.1 to 20 mAmps, preferably about 0.1 to 15 mAmps, preferably about 0.1 to 10 mAmps, preferably about 0.1 to 5 mAmps, preferably about 6 to 20 mAmps, preferably about 10 to 20 mAmps, or preferably about 10 to 16 mAmps.

In embodiments, the pulse width of each pulse is about 0.01 milliseconds to about 6 milliseconds, preferably about 0.01 to 4 milliseconds, preferably about 0.01 to 2 milliseconds, preferably about 0.01 to 1 millisecond, preferably about 0.01 to 0.2 milliseconds, or preferably about 0.01 to about 0.1 millisecond. While not meant to limit the scope of the disclosure, it is believed that for an electrical signal delivered at a frequency of 150 Hz or greater, a pulse width of less than 0.01 milliseconds is not effective to change the activity of the nerve. As discussed above, in embodiments, the parameters of the electrical signal at least partially downregulate activity on the nerve.

In embodiments, the pulses in a set of pulses can be monophasic or biphasic or a mixture of monophasic and biphasic, or some other complex waveform.

In embodiments, the set of pulses at the first selected frequency can be delivered once or more than once during the on time. If a set of pulses is delivered more than once during the on time, the set of pulses are referred to as a burst of signal. In embodiments, there may be a delay period between the sets of pulses. The delay period between each burst may be the same or different. In an embodiment, more than one burst of pulses having a frequency of at least 150 Hz are delivered during an on time. Each burst lasts at least about 26 milliseconds, and each burst is separated by a delay period of at least about 0.3 seconds.

In embodiments, the therapy cycle is a low charge therapy cycle delivering a total charge of 0.2 coulombs or less to the nerve. In embodiments, the total amount of charged delivered in a therapy cycle is about 5 microcoulombs to about 100,000 microcoulombs, more preferably about 10 microcoulombs to about 50,000 microcoulombs, more preferably about 10 microcoulombs to about 10,000 microcoulombs, or more preferably about 10 microcoulombs to about 1000 microcoulombs. In embodiments, the therapy cycle comprising at least one set of pulses having a frequency of at least 150 Hz delivers about 5 microcoulombs of
charge or greater. While not meant to limit the scope of the disclosure, it is believed that a low charge therapy cycle as described herein provides for at least partial downregulation of nerve activity while conserving the energy required to power the therapy cycle. In embodiments, the amount of required energy is decreased so that a primary battery rather than a rechargeable battery may be employed in the systems described herein.

In embodiments, the electrical signal that further comprises: a) a set of pulses applied at a second selected frequency of about 1-10,000 Hz, wherein each pulse of the set of pulses has a pulse width of at least 0.05 microseconds and less than the period of the selected frequency. In embodiments, the second selected frequency is different than the first selected frequency.

The second selected frequency can range from about 1 to about 10,000 Hz. In other embodiments, the first selected frequency has a frequency of about 1 to 1000 Hz, preferably about 1 to 200 Hz, preferably about 1 to 150 Hz, preferably about 1 to 50 Hz, or preferably about 1 to 10 Hz. In an embodiment, the second selected frequency is about 40 Hz or greater, and has a pulse width of about 0.05 microseconds or greater.

In embodiments, the pulse or set of pulses have a current amplitude of about 0.1 to 20 mAmps, preferably about 0.1 to 15 mAmps, preferably about 0.1 to 10 mAmps, preferably about 0.1 to 5 mAmps, preferably about 0.1 to 1 mAmp, preferably about 6 to 20 mAmps, preferably about 10 to 20 mAmps, or preferably about 10 to 16 mAmps.

In embodiments, the pulse width of each pulse is about 0.05 microseconds to about 0.5 second, preferably about 0.1 microseconds to about 0.1 seconds, preferably about 0.5 microseconds to about 0.05 seconds, or preferably about 1 microsecond to .006 seconds.

In embodiments, the pulses in a set of pulses can be monophasic or biphasic or a mixture of monophasic and biphasic, or some other complex waveform.

In embodiments, the set of pulses at the second selected frequency can be delivered once or more than once during the on time. If a set of pulses is delivered more than once during the on time, the set of pulses are referred to as a burst of signal. In embodiments, there may be a delay period between the sets of pulses. The delay period between each burst may be the same or different. In an embodiment,
more than one burst of pulses having a frequency of at less than 150 Hz are
delivered during an on time. In embodiments, each burst has about 1 to about 20
pulses, and lasts at least about 10 microseconds, and each burst is separated by a
delay period of at least 2.5 milliseconds.

In embodiments, the therapy cycle is a low charge therapy cycle delivering a
total charge of 0.2 coulombs or less to the nerve. In embodiments, the total amount
of charged delivered in a therapy cycle is about 5 microcoulombs to about 100,000
microcoulombs, more preferably about 10 microcoulombs to about 50,000
microcoulombs, more preferably about 10 microcoulombs to about 10,000
microcoulombs, or more preferably about 10 microcoulombs to about 1000
microcoulombs. In embodiments, the therapy cycle comprising at least one set of
pulses having a frequency of less than 150 Hz delivers about 5 microcoulombs of
charge or greater.

In embodiments, the set of pulses applied at a first selected frequency of 150
Hz or greater is followed by the set of pulses applied at a second selected frequency
of about 1-10,000 Hz. In other embodiments, the set of pulses applied at a second
selected frequency of about 1-10,000 Hz is followed by the set of pulses applied at a
first selected frequency of 150 Hz or greater. In yet other embodiments, one or more
of the set of pulses may be applied simultaneously or overlapping one another.

In embodiments, an on time of the therapy cycle is at least 30 seconds, more
preferably about 30 seconds to 30 minutes, 30 seconds to 20 minutes, 30 seconds to
10 minutes, 30 seconds to 5 minutes, 30 seconds to 2 minutes, and 30 seconds to 1
minute. In embodiments, the therapy cycle has an offtime during which no signal is
delivered. In embodiments, the time of the off time is selected to allow at least
partial recovery of nerve activity. In embodiments the offtime is at least 30 seconds,
more preferably 30 seconds to 30 minutes, 30 seconds to 20 minutes, 30 seconds to
10 minutes, 30 seconds to 5 minutes, 30 seconds to 2 minutes, and 30 seconds to 1
minute. A therapy cycle can comprises one or more on times and one or more
offtimes. In an embodiment, the therapy cycle includes 2 minutes of on time, 1
minute of off time, 2 minutes of on time, and 5 minutes of off time. While not meant
to limit the scope of the inventive subject matter, it is believed that electrical signals
that are delivered with an on time and an off time minimize gastric accommodation,
decrease discomfort for the patient, and minimize damage to the nerve.
In embodiments, the neuroregulator is configured to deliver one or more than one therapy cycle in a treatment period. A treatment period ranges from about 6 to 24 hours, preferably 6 to 18 hours, 6 to 12 hours, and 6 to 9 hours. In an embodiment, a treatment period is at least 6 hours.

In embodiments, the therapy cycle comprises an electrical signal comprising: a) a set of pulses that have a frequency of about 150 Hz or greater; and b) a total amount of charge delivered to the nerve of about 5 microcoulombs to about 200,000 microcoulombs during the therapy cycle. While not meant to limit the scope of the invention, it is believed that delivering a low amount of charge during a therapy cycle provides effective treatment while saving energy. In embodiments, the electrical signal is applied at a frequency that at least partially downregulates activity on the nerve.

The total amount of charge delivered during the on time of the therapy cycle can be determined based on the pulse width, current amplitude, frequency and total on time of the signal and are related by the following equation:

\[
\text{Total charge per cycle} = (\text{current amplitude}) \times (\text{pulse width}) \times (\text{frequency}) \times (\text{cycle time})
\]

(for biphasic pulses, the total charge is reduced by a factor of 2)

In embodiments, the total amount of charged delivered in a therapy cycle is about 10 microcoulombs to about 100,000 microcoulombs, more preferably about 10 microcoulombs to about 50,000 microcoulombs, more preferably about 10 microcoulombs to about 10,000 microcoulombs, or more preferably about 10 microcoulombs to about 1000 microcoulombs.

In some embodiments, a therapy cycle further comprises one or more electrical signals having a second selected frequency of less than 150 Hz, and an on time of at least 30 seconds. In embodiments, the frequency of about 150 Hz or greater is different than the second selected frequency. During the on time both the frequency of about 150 Hz or greater and the second selected frequency signals are delivered to the nerve. In embodiments, the signal having a frequency of about 150 Hz or greater is referred to as a high frequency signal and the second selected frequency signal is referred to as a low frequency signal.
In some embodiments, the frequency of about 150 Hz or greater of the electrical signal ranges from about 150 to 10,000 Hz, about 200 to 8000 Hz, or about 500 to 5000 Hz. In some embodiments, the frequency of about 150 Hz or greater of the electrical signal is about 500 to 1000 Hz. In embodiments, a signal having a frequency of about 150 Hz or greater comprises a frequency of 200 Hz or greater and include a plurality of charge pulses with pulse widths of about 0.06 to 3000 milliseconds, about 25 to 300 milliseconds, or about 0.06 to 100 milliseconds. In embodiments, a signal having a frequency of about 150 Hz or greater can comprise a frequency of 200 Hz or greater, and have a current amplitude of about 1 to 20 mAmp, about 1 to 6 mAmp, or about 1 to 3 mAmp. In embodiments, a signal having a frequency of about 150 Hz or greater comprises a frequency of 200 Hz or greater, pulse widths of 60 microseconds or greater.

In some embodiments, one or more second selected frequency electrical signal is about 0.5 to 199 Hz, 1 to 150 Hz, or 10 to 100 Hz. In some embodiments, the second selected frequency of the electrical signal is about 10 to 50 Hz. In embodiments, a second selected frequency electrical signal can include a plurality of charge pulses with pulse widths of about 0.025 to 25 microseconds or about 0.05 to about 0.5 microseconds. In embodiments, the low frequency signal comprises packets of 1 to 20 pulses, each pulse having a pulse width of 500 nanoseconds or less. In embodiments, a second selected frequency signal has a frequency of less than 200 Hz and has a current amplitude of 1 mAmp or less. In embodiments, a second selected frequency signal comprises a frequency of less than 200 Hz, and a pulse width of about 100 to 500 nanoseconds. In embodiments, a third selected frequency signal comprises a frequency of less than 200 Hz, and a pulse width of 50 to 500 nanoseconds.

In embodiments, the voltage of each signal can vary. In embodiments of the signal having a frequency of about 150 Hz or greater, the voltage is about 1 to 24 volts. In embodiments, the second selected frequency signal has a voltage of about 1 to 15 volts, or 5 to 15 volts. In embodiments, the second selected frequency signal has a voltage of about 0.1 to about 2 volts, or 0.2 volts to 1 volt.

In some embodiments, additional signals at the low frequency will be numbered numerically, e.g., third selected signal, fourth selected signal, etc. While not meant to limit the scope of the disclosure, it is believed that the combination of
the high frequency signal and a low frequency signal provides at least a partial
downregulation of activity on the nerve.

In embodiments, a therapy cycle comprises one or more additional selected
frequency electrical signals that are delivered simultaneously, precede, follow, or
precede and follow a signal having a frequency of about 150 Hz or greater. In
embodiments, a second selected frequency signal, a third selected frequency signal,
and a signal having a frequency of about 150 Hz or greater can be delivered
simultaneously during an on time of the therapy cycle, each signal having at least
one parameter that differs from the other signals. In embodiments, the second
selected frequency signal can be applied first followed by the signal having a
frequency of about 150 Hz or greater followed by the third selected frequency signal
during an on time. In an embodiment, the second and third selected frequency
signals are initiated and applied throughout the on time and a signal having a
frequency of about 150 Hz or greater is delivered after the initiation of the second
and third selected frequency signals. In an embodiment, a third selected frequency
signal can be applied first and overlap with a signal having a frequency of about 150
Hz or greater, and then the second selected frequency signal continues in concert
with the third selected frequency signal during the on time. In an embodiment, a
second selected frequency signal can be applied first and overlap with a signal
having a frequency of about 150 Hz or greater, and then the third selected frequency
signal is applied during the on time. In embodiments, the second and third selected
frequency signals are applied throughout the on time and the high frequency signal
is delivered once during the on time.

In embodiments, an on time for therapy cycle can range from 1 second to 30
minutes or more, 30 seconds to 5 minutes, from 30 seconds to 10 minutes, or from 1
second to 2 minutes. The on time can optionally include a ramp up and a ramp down
time of about 2 to 60 seconds. The off times of the electrical signal in the therapy
cycle are selected to allow for at least partial recovery of nerve activity. In
embodiments, the off times can be selected from about 30 seconds to about 20
minutes, 1 minute to 10 minutes, or 1 minute to 5 minutes.

The implantable component may be configured to generate therapy cycles
for a treatment period. The therapy cycles can be continuous or intermittent. In some
cases, the treatment period is at least 6 hours. In embodiments, a treatment period is
from 30 minutes to 24 hours, 30 minutes to about 12 hours, 30 minutes to 9 hours, 30 minutes to 8 hours, or 30 minutes to 6 hours. In embodiments, a therapy cycle comprises 30 minutes of continuous electrical signal treatment on time with no off times. In embodiments, the external programmer is configured to provide therapy instructions that include multiple therapy cycles per treatment period. The external programmer may also provide for one or more than one treatment periods per day or per week. In some embodiments, treatment periods may be related to the period of time before and after eating of a meal.

Normally a patient would only use the device while awake. The hours of therapy delivery can be programmed into the device by the clinician (e.g., automatically turns on at 7:00 AM and automatically turns off at 9:00 PM). In the RF-powered version of the neuroregulator, use of the device is subject to patient control. For example, a patient may elect to not wear the external antenna. The device keeps track of usage by noting times when the receiving antenna is coupled to the external antenna through radio-frequency (RF) coupling through the patient's skin.

The flexibility to vary average vagal activity gives an attending physician great latitude in treating a patient. For example, in treating obesity, the electrical signal can be applied with a short "off" time to reduce weight as rapidly as possible. The parameters may be varied in accord with the weight loss occurring over time. The system provides data with regard to actual patient use and therapy delivery time and such data can be used to modify the parameters of the therapy cycle. For example, the number of therapy cycles may be initially much higher when the patient has more weight to lose and may be adjusted downward to a maintenance mode once the weight loss goal is achieved. The therapy may be discontinued for a period of time if the patient continues to lose weight beyond the goal weight loss.

If the patient experiences discomfort due to dysmotility, the duration of the "off" period can be increased to improve patient comfort. Also, the reduction of enzyme production can result in decreased fat absorption with consequential increase of fat in feces. The on and off duration can be adjusted to achieve tolerable stool (e.g., avoiding excessive fatty diarrhea). The control afforded by the present invention can be used to prevent the enteric nervous system's assumption of control
since vagal activity is not completely interrupted as in the case of a surgical and permanent vagotomy.

While patient weight loss and comfort may be adequate, as feedback for determining the proper parameters for duration of on time and off time, more objective tests can be developed. For example, the duration of on time and off time can be adjusted to achieve desired levels of enzyme production and nutrient digestion. In one example of drug therapy for obesity, orlistat blocks the action of lipase. Lipase is a fat-digesting enzyme. As a consequence of this reduction in lipase, the fat content of feces increases. It is generally regarded as desirable to modulate drug intake so that fecal fat does not exceed 30% of ingested fat. Similarly, the on and off time durations can be modulated to achieve the same result. Such testing can be measured and applied on a per patient basis or performed on a statistical sampling of patients and applied to the general population of patients.

In embodiments, the parameters of the therapy cycle can be selected based on the starting blood pressure of the subject, such as a systolic blood pressure of at least 140 mmHg or a diastolic blood pressure of 90 mmHg. In embodiments, if the amount of change in systolic blood pressure is less than 5 mmHg, parameters and/or therapy cycles are adjusted to decrease blood pressure at least 10 mmHg. Parameters and/or therapy cycles may be adjusted once or more than once in order to reach a systolic blood pressure of at least 130 mmHg.

In another embodiment, the parameters of the therapy cycle are selected based on the Patients with Type 2 diabetes have a fasting plasma glucose of 126 mg/dl or greater; oral glucose tolerance of 200 mg/dl or greater; and/or % of HbAIC of 6.5% or greater. In some cases, the HbAIC percentage is 6-7%, 7-8%, 8-9%, 9-10%, and greater than 10%. In embodiments, if the amount of change in % of HbAIC is less than 0.5% parameters and/or therapy cycles are adjusted to decrease % of HbAIC at least 1%. Parameters and/or therapy cycles may be adjusted once or more than once in order to reach a % of HbAIC of at least 7%.

In some embodiments, a sensing electrode SE is added to the system to monitor vagal activity as a way to determine how to modulate the on and off time durations. While a sensing electrode can be an additional electrode, it will be appreciated a single electrode could perform both functions. The sensing and therapy electrodes can be connected to a neuroregulator as shown in FIG.3. When
the sensing electrode SE yields a signal representing a targeted maximum vagal activity or tone (e.g., 50% of baseline) the neuroregulator with the additive function of receiving a signal from the sensing electrode energizes the electrode with a signal. As described with reference to neuroregulator 104, neuroregulator with the additive function of receiving a signal from the sensing electrode can be remotely programmed as to parameters of on duration and off duration as well as targets for initiating a therapy cycle.

The apparatus and method described herein use recovery of the vagus nerve to control a degree of down-regulation of vagal activity. This gives a physician enhanced abilities to control a patient’s therapy for maximum therapeutic effectiveness with minimum patient discomfort. Therefore, the vagal modulation of the present invention can be used as treatment for other conditions associated with excess weight.

3) **Methods in combination**

The disclosure provides methods for treating a condition associated with excess weight that include administering to a subject a composition comprising an agent that affects weight loss, blood pressure, and/or blood sugar.

In some embodiments, the agent will increase energy expended and/or decrease the amount of energy consumed. Agents that affect weight loss are known to have certain characteristics, for example, some agents enhance the sensation of satiety, other agents decrease appetite (anorexic), others block the absorption of fat or other nutrients, others inhibit enzymes that digest fat, some agents are thermogenic, and some have combinations of effects.

Agents that affect weight loss can be selected based on an ability to complement treatment of applying a signal to downregulate neural activity of the vagal nerve. Drugs that have been approved by the FDA to treat obesity include sibutramine and orlistat for long term use; and phentermine for short term use. However, the excess weight loss associated with administration of these drugs is limited to a maximum of about 10% when compared with loss due to diet and exercise alone. As described herein, an agent is selected that may provide a complementary or synergistic effect with the application of signal to modulate neural activity on the vagus nerve. A synergistic or complementary effect can be
determined by determining whether the patient has an increase in excess weight loss as compared to one or both treatments alone. In some embodiments, agents that act at a different site (e.g. hypothalamus or pituitary) or through a different pathway may be selected for use in the methods described herein. Agents that complement treatment are those that include a different mechanism of action for affecting the excess weight of the subject.

An agent may also or in addition be selected to administer that may have undesirable side effects at the recommended dosage that prevents use of the agent, or that prevents compliance by the patient. In addition, patients that have excess weight as well as hypertension, cardiac conditions, liver disease, or renal disease may not be able to tolerate treatment with one or more of the agents at the recommended dosage due to adverse side effects. Agents that have undesirable side effects include fenfluramine, and dexfenfluramine which have been shown to have adverse effects on blood pressure and to be associated with valvular heart disease.

Other drugs such as bupropion can cause seizures. Drugs that inhibit fat absorption, such as orlistat, can cause diarrhea, soft and oily stools, and flatulence. Other drugs may cause central nervous system symptoms such as anxiety, cognitive deficits, depression, and/or nervousness.

Combining administration of a drug with undesirable side effects with modulating neural activity on the vagus nerve may allow for administration of the drugs at a lower dose thereby minimizing the side effects. In addition, a drug may be selected that has altered pharmacokinetics when absorption is slowed by a delay in gastric emptying due to neural downregulation as described herein. In other embodiments, the recommended dosage may be lowered to an amount that has fewer adverse side effects. In some embodiments, the therapeutic window may be increased. In some embodiments, a drug that may be useful for short term use may be administered for long term use at the lowered dosage. For example, a drug such as rimonabant at 20 mg per dose may be lowered to a 5 mg dose and still be effective for weight loss. In embodiments, it is expected that the recommended dosage may be able to be lowered at least 25%. In other embodiments, the dosage can be lowered to any percentage of at least 25% or greater of the recommended dose. In some embodiments, the dosage is lowered at least 25, 30, 35, 40, 45, 50, 55, 60, 65, 70, 75, 80, 85, 90, 95, or 100% of the recommended dosage.
Agents that affect the hypothalamic or neuroendocrine function such as ghrelin, ghrelin agonists, ghrelin antagonists, leptin agonist, leptin antagonists, ciliary neurotrophic factor (CNTF), CNTF analogues, amylin, and amylin analogues may complement effects on the vagus nerve. In addition, agents that enhance the sensation of satiety and reduce appetite and act on neurotransmitters in the brain may complement the effects of neural downregulation on the vagus nerve. Such agents include neurotransmitter releasers, inhibitors of the uptake of serotonin, norepinephrin, and dopamine. These agents include, for example, sibutramine, fenfluramine, phentermine, dexphenfluoramine, flouxetine, and bupropion. Agents that are thermogenic increase energy expenditure of the patient and would have a complementary effect to that of modulating the neural activity of the vagus nerve. These agents include, for example, sibutramine, leptin, leptin agonists, leptin analogues, CNTF, and CNTF analogues. Agents that suppress appetite and enhance the feeling of satiety include incretins including GLP-1, PYY, CKK, and oxyntomodulin.

In the methods of the disclosure, an anorexic agent may be administered. Several anorexic agents are known to those of skill in the art. Anorexic agents include phentermine, fenfluramine, dextfenfluramine, endocannabinoid receptor antagonists, ghrelin antagonists, orexin antagonists, somatostatin receptor agonist, GLP-1, PYY, and cholecystokinin agonists. Endocannabinoid receptor antagonists are known and include rimonabant. Phentermine has been approved for short term treatment of obesity.

Thermogenic agents are attractive as they increase the energy expenditure of the subject. Leptin, for example, may reduce calorie intake and increases energy expenditure through action on the sympathetic nerve system. Other agents that have thermogenic characteristics include sibutramine, leptin, leptin agonist, a leptin analogue, ciliary neurotrophic factor (CNTF), and a CNTF analogue. Axokine is a CNTF analogue that has been shown to promote weight loss. Sibutramine has been approved for long term treatment of obesity.

Agents that inhibit fat absorption are more likely to have effects similar to that of modulating neural activity of the vagus nerve rather than complementary effects. Even though the action of agents that inhibit fat absorption may not be complementary to downregulation of vagal nerve activity, they have undesirable
side effects that may contribute to a lack of patient compliance. Such side effects include diarrhea, flatulence and loose stools. Some agents inhibit the action of lipases that break down fat in ingested food. Agents that inhibit fat absorption include orlistat or a lipin inhibitor. Orlistat has been approved for long term treatment of obesity.

Agents that enhance satiety through a CNS pathway, such as a hypothalamic or neuroendocrine pathway, would have effects complementary to those due to treatment by modulating neural activity on the vagus nerve. Agents that enhance satiety include somatostatin receptor agonists, GLP-1 agonists, GLP-1 variants, peptide PYY, POMC agonists, neuropeptide Y inhibitors, tipiramate, tegretol, bupropion, naltrexone, zonisamide, amylin, amylin analogues, and oxyntomodulin. Pramlitidine is an amylin analogue that has shown effectiveness in clinical trials for weight loss. Exendin-4 is a potent and long lasting GLP-1 analogue and agonist of GLP-1. Liraglutide is also a long acting analogue of GLP-1. Administration of PYY increases proiomelanocortin activity and has been shown to result in decreased food consumption. Oxyntomodulin suppresses appetite and food intake.

Sequences for the polypeptides such as GLP-1, ghrelin, leptin are known to those of skill in the art and are described in publicly available databases. Representative sequences are: Leptin(gl 1469860 and gl4557715); ghrelin (gl 37183224); POMC (Gl 190188); GLP-1(gl 125987831 (P01275)); CKKB receptor (gl 417029); CNTF (gl 633830, gl 825643, gl 16585); PYY (gl 71361686, gl 1172776); orexin (gl 4557635); somatostatin receptor (gl 431095, gl 307430) and amylin (gl 457131, gl 4557655).

In some embodiments, the patient has a condition associated with excess weight including obesity, compulsive eating, and/or bulimia. In some embodiments, a patient may be selected that is not yet obese but is overweight. Excess weight of at least 10 pounds or 10-20 pounds is associated with adverse health effects. Overweight and obesity classifications include those determined by body mass index (BMI) (calculated as weight in kilograms divided by the square of height in meters). For example, normal weight: BMI = 18.5-24.9; overweight: BMI = 25.0-29.9; obesity-class 1: BMI = 30.0-34.9; obesity-class 2: BMI = 35.0-39.9; obesity-class 3: BMI ≥ 40.0. Of course these ranges may vary given the height, gender, and age of the subject. In other embodiments, the patient at least has a body mass index (BMI)
of at least 25 or greater. In other embodiments, the patient has a BMI of at least 27
5 to about 30 and also has other health conditions such as hypertension, diabetes,
cardiovascular disease, liver disease, and/or renal disease. In other embodiments,
the patient is overweight at least 10 pounds and/ or has a condition such as type II
diabetes, asthma, arthritis, hypertension, high cholesterol, and/or cardiovascular
disease.

The disclosure provides methods for treating a condition associated with impaired glucose regulation that include neuroregulation as well as administering to a subject a composition comprising an agent that affects glucose control in a subject. In some embodiments, the agent increases the amount of insulin present in the blood. In other embodiments, the agent increases insulin sensitivity. In some embodiments, the agent reduces endogenous glucose production and/or glucose absorption.

Several pathways are known to affect energy balance. Pathways include gut-
hypothalamic axis (e.g. ghrelin), gut-hindbrain axis (e.g. vagus nerve), peripheral
tissue (adipose tissue, skeletal muscle)-hypothalamic axis (e.g. leptin), and hypothalamic-hindbrain axis (neural projections). In particular, the hypothalamus (forebrain) and the area postrema (hindbrain) are 2 regions of the central nervous system which are thought to play orchestrating roles in the human energy homeostasis. It has been documented that there are neural connections between these two regions enabling communications and complementary, as well as, redundant effects on body energy balance. Numerous hormones, enzymes, neurotransmitters, and other mediators are released from different parts of these pathways and can have influences on these regions of the central nervous system. Utilization of distinct treatment modalities that involve different parts of these pathways and brain regions, thus altering the communication between the central nervous system and gut, pancreas, liver, muscle, and fat cells may be of importance in combinatorial therapy that is highly effective, robust, and durable.

Agents that affect impaired glucose control can be selected based on an ability to complement treatment of applying a signal to alter neural activity of a target nerve. As described herein, an agent is selected that may provide a complementary or synergistic effect with the application of signal to modulate neural activity on a target nerve such as the vagus nerve. A synergistic or
complementary effect can be determined by determining whether the patient has an improvement in glycemic control as described herein as compared to one or both treatments alone.

In some embodiments, agents that act at a different site (e.g. hypothalamus or pituitary) or through a different pathway may be selected for use in the methods described herein. Agents that complement treatment are those that include a different mechanism of action for affecting the glycemic control of the subject. In some embodiments, a synergistic effect may be observed with an agent that does not affect glucose digestion and/or delay gastric emptying, such as an agent that increases insulin secretion, insulin sensitivity, and/or decreases endogenous glucose production. Such agents include insulin, amylin analogues, insulin secretagogues, sulfonylureas, meglitinides and PPAR alpha, gamma and delta agonists.

An agent may also or in addition be selected to be administered that may have undesirable side effects at the recommended dosage that prevents use of the agent, or that provides inadequate glycemic control. In addition, patients that have hypertension, cardiac conditions, liver disease, or renal disease may not be able to tolerate treatment with one or more of the agents at the recommended dosage due to adverse side effects.

Agents that have undesirable side effects include Avandia (rosiglitazone; PPAR-gamma agonist) which has been shown to have adverse effects on cardiovascular conditions and cause weight gain. Drugs that inhibit or slow gastric emptying, such as amylin analogs or GLP-1 analogs, or drugs that are irritants to the GI track, such as metformin (biguanide) can cause nausea, vomiting, and diarrhea. Drugs that alter breakdown and absorption of carbohydrate in the GI track, such as Precose (acarbose; alpha-glucosidase inhibitor) can cause diarrhea and flatulence. Drugs that increase blood insulin concentrations, such as exogenous insulin administration, sulfonylureas, and meglitinides can cause hypoglycemia and weight gain.

The disclosure provides methods for treating a condition associated with impaired blood pressure and/or heart rate that include administering to a subject a composition comprising an agent that affects blood pressure and/or heart rate in a subject. In some embodiments, the patients may be refractory to one or more pharmaceuticals for treatment of elevated blood pressure. In that case, modulation of
vagal nerve activity may be employed without administration of other agents. In other cases, for patients refractory to one or more drugs a combination of modulation of vagal nerve activity with administration of one or more agents may be beneficial. In other embodiments, a drug used to treat a cardiac condition may be associated with hypotensive effects and therefore the drug may be administered with an electrical treatment signal that increases blood pressure.

Agents that affect impaired blood pressure control can be selected based on an ability to complement treatment of applying a signal to alter neural activity of a target nerve. As described herein, an agent is selected that may provide a complementary or synergistic effect with the application of signal to modulate neural activity on a target nerve such as the vagus nerve. A synergistic or complementary effect can be determined by determining whether the patient has an improvement in blood pressure and/or heart rate as described herein as compared to one or both treatments alone.

In some embodiments, agents that act at a different site or through a different pathway may be selected for use in the methods described herein. Agents that complement treatment are those that include a different mechanism of action for affecting the heart rate and/or blood pressure control of the subject.

An agent may also or in addition be selected to be administered that may have undesirable side effects at the recommended dosage that prevents use of the agent, or that provides inadequate blood pressure control. In addition, patients that have cardiac conditions, liver disease, or renal disease may not be able to tolerate treatment with one or more of the agents at the recommended dosage due to adverse side effects.

Combining administration of a drug with undesirable side effects with modulating neural activity on a target nerve may allow for administration of the drugs at a lower dose thereby minimizing the side effects, may allow for administration of a single drug instead of multiple drugs, or may allow administration of higher doses of the drugs. In addition, a drug may be selected that has altered pharmacokinetics when absorption is slowed by a delay in gastric emptying due to neural downregulation as described herein. In other embodiments, the recommended dosage may be lowered to an amount that has fewer adverse side effects. In embodiments, it is expected that the recommended dosage may be able to
be lowered at least 25%. In other embodiments, the dosage can be lowered to any percentage of at least 25% or greater of the recommended dose. In some embodiments, the dosage is lowered at least 25, 30, 35, 40, 45, 50, 55, 60, 65, 70, 75, 80, 85, 90, 95, or 100% of the recommended dosage.

In an embodiment, a method provides a treatment for a condition associated with impaired blood pressure and/or heart rate. Conditions associated with impaired blood pressure and/or heart rate include, hypertension, prehypertension, congestive heart failure, ischemic heart disease, coronary artery disease, chronic renal disease, and cerebral vascular disease. A method comprises selecting a drug useful for treating hypertension or congestive heart failure and having a recommended dosage for efficacy where a patient is likely to experience disagreeable side effects at said recommended dosage; and treating the patient with a concurrent treatment comprising: applying an intermittent neural block to a target nerve of the patient at multiple times per day and over multiple days with the block selected to down-regulate afferent and/or efferent neural activity on the nerve and with neural activity restoring upon discontinuance of said block; and administering said drug to the patient at a dosage less than said recommended dosage. In some embodiments, the effective dosages for such a patient are associated with disagreeable side effects contributing to said patient not complying with a drug treatment. In some embodiments, patients are those that have cardiac conditions, liver, or renal disorder and may not be able to tolerate treatment with one or more of the agents.

A method comprises selecting a drug useful for treating a cardiac condition and having a recommended dosage for efficacy where a patient is likely to experience disagreeable side effects at said recommended dosage such as hypotension; and treating the patient with a concurrent treatment comprising: applying an intermittent neural conduction signal to a target nerve of the patient at multiple times per day and over multiple days with the signal selected to up-regulate neural activity and with neural activity restoring upon discontinuance of said signal; and administering said drug to the patient at a dosage less than said recommended dosage. In embodiments, the target nerve is the vagus nerve at a location below vagal innervation of the heart.
A number of oral and parenteral medications are available for the treatment of hypertension. Some of these medications are also commonly employed for the treatment of congestive heart failure.

Beta-blockers (beta-adrenergic blockers) work by reducing sympathetic nerve input to the heart. Thus, the heart beats less often per minute and with less force. Subsequently, the heart reduces its work, and blood pressure drops. Beta-blockers include propranolol, metoprolol, atenolol, and many others. Alpha-blockers (alpha-adrenergic blockers) target the nervous system to relax blood vessels, allowing blood to pass more easily. Examples of alpha blockers are doxazosin, prazosin, and terazosin. Alpha-beta-blockers (alpha- and beta-adrenergic blockers) basically have the same effect as a combined alpha-blocker and beta-blocker. They target the nervous system to relax the blood vessels, as well as work to slow the heartbeat. As a result, less blood is pumped through wider vessels, decreasing the overall blood pressure. Alpha-beta-blockers include labetalol and carvedilol.

Diuretics cause the body to excrete water and salt. This leads to a reduction in plasma volume, which subsequently lowers systemic blood pressure. Diuretics include furosemide, hydrochlorothiazide, and spironolactone.

Angiotensin Converting Enzyme (ACE) inhibitors work by preventing the body's production of angiotensin II, a hormone that normally causes blood vessels to narrow. Consequently, the vessels remain wider, which lowers blood pressure. Angiotensin II also normally stimulates the release of another hormone, called aldosterone, which is responsible for the body's retention of sodium. Hence, in addition to creating wider vessels, ACE inhibitors mimic the effect of diuretics to a certain extent. As a result, blood vessels are subject to less pressure, and the heart performs less work. Examples of ACE inhibitors include enalapril, captopril, and lisinopril. Angiotensin II antagonists are primarily used for patients who develop a cough as a side effect of taking ACE inhibitors. This medication antagonizes angiotensin II, thus inhibiting its effects. Examples include losartan and valsartan.

Calcium channel blockers keep calcium from entering the muscle cells of the heart and blood vessels. The heart and vessels relax, allowing blood pressure to go down. Some calcium channel blockers are nifedipine, verapamil, and diltiazem.

Vasodilators work by relaxing the muscle in the blood vessel wall. Hydralazine and minoxidil are both generic forms of vasodilators.
Dosages for administration to a subject can readily be determined by one of skill in the art. Guidance on the dosages can be found, for example, by reference to other drugs in a similar class of drugs. For example, dosages have been established for any of the approved drugs or drugs in clinical trials and the range of dose will depend on the type of drug. For example, pramlintide dosages range from about 240 micrograms up to 720 micrograms per day. A dosage of sibutramine of 5 to 20 mg per day is recommended.

Dosages associated with adverse side effects are known or can also be readily determined based on model studies. For example, dosages of 30 mg per day or greater of fenfluramine in combination with dexphenfluramine were associated with valvular heart conditions. Risk of seizures and increase in blood pressure with bupropion treatment increases at doses of 300 mg per day or greater. A determination of the effective doses to achieve excess weight loss while minimizing side effects can be determined by animal studies.

The agents or drugs will be formulated, dosed, and administered in a fashion consistent with good medical practice. Factors for consideration in this context include the particular disorder being treated, the particular mammal being treated, the clinical condition of the individual patient, the age of the patient, other medications that the patient is taking, the cause of the disorder, the site of delivery of the agent, the method of administration, the scheduling of administration, and other factors known to medical practitioners. The agent need not be, but is optionally formulated with one or more agents currently used to prevent or treat the disorder in question. The effective amount of such other agents depends on the amount of agent that alters an energy balance of the subject present in the formulation, the type of disorder or treatment, and other factors discussed above. These are generally used in the same dosages and with administration routes as used hereinbefore or about from 1 to 99% of the heretofore employed dosages.

The agents or drugs can be administered at the same time that the subject is receiving a therapy signal treatment, after therapy signal treatment has been administered and is ongoing, when therapy signal treatment is providing for maintenance of weight loss. For example, the implantable device can be implanted and the subject undergoes therapy for a period of at least 1 month to determine the rate of excess weight loss using the device. The rate and amount of excess weight
loss using the implantable device can be determined and if weight loss is not adequate (e.g., less than 1% excess weight loss) then the therapy cycle parameters may be adjusted and/or an agent that affects weight loss can be administered. In most cases, the implantable device will deliver therapy for a period of time before the agent is administered to the subject. An agent that affects weight loss may be administered in those patients that appear to be low responders or intermediate responders to the electrical signal treatment.

Therapeutic formulations comprising the agent are prepared for storage by mixing the agent having the desired degree of purity with optional physiologically acceptable carriers, excipients or stabilizers (Remington's Pharmaceutical Sciences 16th edition, Osol, A. Ed. (1980)), in the form of aqueous solutions, lyophilized or other dried formulations. Acceptable carriers, excipients, or stabilizers are nontoxic to recipients at the dosages and concentrations employed, and include buffers such as phosphate, citrate, histidine and other organic acids; antioxidants including ascorbic acid and methionine; preservatives (such as octadecyldimethylbenzyl ammonium chloride; hexamethonium chloride; benzalkonium chloride, benzethonium chloride; phenol, butyl or benzyl alcohol; alkyl parabens such as methyl or propyl paraben; catechol; resorcinol; cyclohexanol; 3-pentanol; and m-cresol); low molecular weight (less than about 10 residues) polypeptides; proteins, such as serum albumin, gelatin, or immunoglobulins; hydrophilic polymers such as polyvinylpyrrolidone; amino acids such as glycine, glutamine, asparagine, histidine, arginine, or lysine; monosaccharides, disaccharides, and other carbohydrates including glucose, mannose, or dextrins; chelating agents such as EDTA; sugars such as sucrose, mannitol, trehalose or sorbitol; salt-forming counter-ions such as sodium; metal complexes (e.g., Zn-protein complexes); and/or non-ionic surfactants such as TWEEN™, PLURONICSTM or polyethylene glycol (PEG).

The formulation herein may also contain more than one active compound as necessary for the particular indication being treated. In certain such embodiments, the compounds have complementary activities that do not adversely affect each other. Such molecules are suitably present in combination in amounts that are effective for the purpose intended.
The therapeutic agent is/are administered by any suitable means, including parenteral, subcutaneous, orally, intradermal, intraperitoneal, and by aerosol. Parenteral infusions include intramuscular, intravenous, intraarterial, intraperitoneal, or subcutaneous administration. Pumps may be utilized as well as drug eluting devices and capsules.

Modifications and equivalents of disclosed concepts such as those which might readily occur to one skilled in the art are intended to be included in the scope of the claims which are appended hereto. For example, while the foregoing example is described with reference to applying signals to vagus nerves to treat obesity, the invention is applicable to other conditions associated with excess weight amenable to treatment by down-regulating or otherwise modulating activity of the vagus nerve.

In the sections of this application pertaining to teachings of the prior art, the specification from prior art patents is substantially reproduced for ease of understanding the embodiment of the present invention. For the purpose of the present application, the accuracy of information in those patents is accepted without independent verification. Any publications referred to herein are hereby incorporated by reference.
What is claimed is:

1. A system for treating a gastrointestinal disorder or a condition associated with excess weight of a subject comprising:
   - at least one electrode configured to be implanted within a body of the patient and placed at a vagus nerve, the electrode also configured to apply therapy to the vagus nerve upon application of a therapy cycle to the electrode;
   - an implantable neuroregulator for placement in the body of the patient beneath the skin layer, the implantable neuroregulator being configured to generate a therapy cycle, wherein the therapy cycle comprises an on time during which an electrical signal is delivered, the electrical signal comprising:
     - a) a set of pulses applied at a first selected frequency of about 150-10,000 Hz, wherein each pulse of the set of pulses has a pulse width of at least 0.01 milliseconds and less than the period of the first selected frequency.

2. A system for treating a gastrointestinal disorder or a condition associated with excess weight of a subject comprising:
   - at least one electrode configured to be implanted within a body of the patient and placed at a vagus nerve, the electrode also configured to apply therapy to the vagus nerve upon application of a therapy cycle to the electrode;
   - an implantable neuroregulator for placement in the body of the patient beneath the skin layer, the implantable neuroregulator being configured to generate a therapy cycle, wherein the therapy cycle comprises an on time during which an electrical signal is delivered, the electrical signal comprising:
     - a) a set of pulses that have a frequency of about 150 Hz or greater; and
     - b) a total amount of charge delivered to the nerve of about 5 microcoulombs to 200,000 microcoulombs during the therapy cycle.

3. A system according to claim 1 or claim 2, wherein the implantable neuroregulator further comprises a power source.
4. The system according to any one of claims 1 to 3, wherein the power source is a primary battery or a rechargeable battery.

5. The system according to any one of claims 1 to 4, further comprising an external charger adapted to communicate therapy instructions and power to the neuroregulator, wherein the implantable neuroregulator is adapted to communicate with the external charger.

6. The system according to any one of claims 1 to 5, wherein the therapy cycle comprises an electrical signal that further comprises: a) a set of pulses applied at a second selected frequency of about 1-10,000 Hz, wherein each pulse of the set of pulses has a pulse width of at least 0.05 microseconds and less than the period of the second selected frequency.

7. The system according to claim 6, wherein the set of pulses applied at a first selected frequency of 150 Hz or greater is followed by the set of pulses applied at a second selected frequency of about 1-150 Hz.

8. The system of any one of claims 6 to 7, wherein the set of pulses applied at a first selected frequency of 150 Hz or greater has a frequency of 1000 Hz or greater, and wherein the set of pulses applied at a second selected frequency of about 1 to 10,000 Hz have a frequency of 40 Hz or greater.

9. The system of any one of claims 1 to 8, wherein the set of pulses at a first selected frequency and at a second selected frequency have a current of 0.1 to 20 mAmps, and a total delivered charge of about 200,000 microcoulombs or less.

10. The system of claim 9, wherein the set of pulses are applied at a first selected frequency of 150 Hz or greater, a pulse width of at least 0.09 milliseconds, and a current of about 6 to 20 mAmps, and wherein the set of pulses applied at a second selected frequency of 40 Hz or greater comprise a plurality of a set of about 1 to 20 pulses, each pulse having a pulse width of about 0.05 to 0.5 microseconds, and a delay period between the each set of pulses of 2.5 milliseconds or greater.
11. The system of claim 9 or claim 10, wherein the set of pulses applied at a first selected frequency of 1000 Hz or greater comprises a plurality of a set of pulses, wherein each set of pulses is delivered in at least about 26 milliseconds or greater and with a delay period between each set of pulses of 0.3 seconds or greater.

12. The system of any one of claims 1 to 11, wherein the therapy cycle has an off time, wherein the off time is an amount of time that allows at least partial recovery of the nerve.

13. The system any one of claims 1 to 12, wherein the therapy cycle comprises an electrical signal having a first selected frequency of at least 200 Hz, an electrical signal having a second selected frequency of less than 200 Hz, and an on time of at least 30 seconds.

14. The system of any one of claims 1 to 13, wherein the implantable neuroregulator is configured to deliver therapy for a treatment period.

15. The system of claim 14, wherein the treatment period is at least 6 hours.

16. The system of any one of claims 1 to 15, wherein the external charger is configured to provide therapy instructions to the neuroregulator comprising multiple therapy cycles in a treatment period.

17. The system of any one of claims 1 to 16, further comprising an external programmer.

18. The system of claim 17, wherein the external programmer is configured to obtain patient data, wherein the patient data comprises data obtained from the implantable component concerning actual therapy delivered, and patient data concerning the health profile of the patient.
19. The system of claim 18, wherein the health profile comprises the presence or absence of conditions selected from the group consisting of diabetes, hypertension, cardiac condition, liver disorder, a renal disorder and combinations thereof.

20. A method of selecting parameters for a therapy cycle for an implantable device in a subject comprising:
   a) selecting parameters of a therapy cycle, wherein the therapy cycle comprises an electrical signal comprising:
      i) a set of pulses applied at a first selected frequency of about 150-10,000 Hz, wherein each pulse of the set of pulses has a pulse width of at least 0.01 milliseconds and less than the period of the first selected frequency;
   b) communicating the selected parameters to the implantable device comprising the system of claim 1; and
   c) determining the amount of actual therapy delivered over a time period and adjusting the parameters of the therapy cycle to achieve delivery of at least 6 hours of treatment or adjusting the other parameters of the therapy cycle or both to increase the amount of excess weight loss, to affect the blood pressure, and/or diabetes of the subject.

21. The method of claim 20, further comprising selecting the parameters of the therapy cycle based on the starting body mass index of the subject.

22. The method of claim 21, wherein the subject has a body mass index of at least 25 or greater.

23. The method of claim 20, further comprising selecting the parameters of the therapy cycle based on the starting blood pressure of the subject.

24. The method of claim 23, wherein the subject has a systolic blood pressure of at least 140 mmHg.
25. The method of claim 20, further comprising selecting the parameters of the therapy cycle based on the starting % HbAlC of the subject.

26. The method of claim 25, wherein the subject has a % of HbAl C of 6.5% or greater.

27. A method of treating a gastrointestinal disorder or a condition associated with excess Weight in a subject comprising:
   - applying an electrode to a vagus nerve at a location below vagal innervation of the heart;
   - applying a therapy cycle to the vagus nerve, wherein each therapy cycle comprises a high frequency electrical signal having a first selected frequency of at least 150 Hz, a low frequency electrical signal having a second selected frequency of less than 150 Hz, an on period of at least 30 seconds, and an off period, wherein the off period is selected to allow at least partial recovery of nerve activity.

28. The method according to claim 27, wherein the first selected frequency of the high frequency electrical signal is at least 1000 Hz.

29. The method according to any one of claims 27 to 28, wherein the frequency of the low frequency electrical signal is at least 40 Hz.

30. The method according to any one of claims 27 to 29, wherein the low frequency signal precedes the high frequency signal and follows the high frequency signal.

31. The method according to any one of claims 27 to 30, wherein the parameters further comprises a treatment period of at least 6 hours.

32. The method according to any one of claims 27 to 31, wherein the condition is selected from the group consisting of obesity, hypertension, diabetes, and combinations thereof.
33. The method of any one of claims 27 to 32, further comprising administering one or more agents that treat the gastrointestinal condition or affect weight loss.

34. The method of claim 33, wherein the agents that affect weight loss comprise agents that enhance the sensation of satiety, agents that decrease appetite, agents that block the absorption of fat or other nutrients, agents that inhibit enzymes that digest fat, agents that are thermogenic, or combinations thereof.
